Introduction

In 2016, a comprehensive explanatory model was developed that offers the possibility to appoint all functional perception processes involved in any conceivable goal-directed motor action. It provides a universal explanation, demonstrating that the execution of any action always requires the simultaneous perception of three autonomous foci. Whether it involves catching a ball, the grasping of a coffee cup or throwing a ball towards a basket, one autonomous focus continuously tracks the movement of the ball, the coffee cup and the basket as the environmental object, universally representing a catching action. The other two autonomous foci are concerned with perceiving the movement within the egocentrically executed action: i.c., the movement of the hand (fingertips) or the basketball along an action trajectory shape (towards the ball, the coffee cup or the basket), which universally represents a throwing action.

In relationship to which it compels a fact that, within our worldly dimensions, the sequential positions P of any conceivable object are always interconnected c.q. must always sprout from each other. This factually means that, for example, with an incoming tennis ball within a catching action, the perceptions of all positions P of the tennis ball will always form a line c.q. will always represent solely one line segment shape. This limits the perception to such an extent that we can already precisely know within which global fluctuation boundaries the actual catching will have to take place. According to which it is important to realize that all manifest positions of the tennis ball create the actual line shape, but more essentially, the latent part of the tennis ball's action trajectory shape must (!) emerge from the manifest part.

This applies not only to catching actions but to all throwing actions as well. So also within a free throw in basketball, all positions of the basketball will always be interconnected and construct just one sole action trajectory shape, will the current position of the basketball always represent the precise division between the manifest and latent parts of the outgoing ball trajectory shape, and must the latent part of the action trajectory also (!) emerge from the manifest part. Which facts are clearly not to be refuted.

The explanatory model is based on the paradigm that, in its evolutionary development, the perceptual organ first functioned as a comparison mechanism that could record the autonomous movement of the animal and the autonomous movement of the environment c.q. the environmental objects in line segment shapes. In relationship to which it is important to emphasize that the ability to perceive movement arose long before the more advanced cognitive skills were developed that gave us insight into the

nature of what exactly moves¹. Thus, perceiving movement essentially has nothing to do with perceiving what exactly moves, and it can also be established that perceiving mere movement must be placed close to the origin of the evolutionary development of the perception processes.

This premise aligns entirely with the findings of J.J. Gibson, who, in addition to indicating the autonomy of the animal, also indicates the autonomy of the environment, while also showing that in the execution of every action, a touching process between the animal and the environment always takes place. If we then take the aforementioned paradigm as a starting point for the execution of a goal-directed action, it can be shown that the animal and the environmental object must at least come into contact with each other first in most motor actions. Which within our perception processes means that 1. a perceptual image of the movement of the environmental object within an action trajectory shape of the catching action, and 2. a perceptual image of the egocentric movement of the animal within an action trajectory shape of the throwing action, will at least have to lead to a perceptual image of a latent intersection point of those two line segment shapes.

As within any conceivable action then solely two universal possibilities arise:

- 1. The environmental object (e.g., the basket or the tennis ball) is standing still². The perception records this as a zero-movement within a zero-line segment shape within the catching action, and a perceptual image of a latent egocentric action trajectory shape of the basketball within the throwing action must be formed to construct a perceptual image of an intersection point of the two involved action trajectory shapes.
- 2. The environmental object (e.g., the basket or the tennis ball) is moving (towards us). The perception records this as a movement within an incoming action trajectory shape within the catching action. This also necessitates forming a perceptual image of a latent egocentric action trajectory shape of the basketball. Which finally should lead to the creation of an autonomous perceptual image of a future (latent) intersection point sprouting from the two latent parts of the involved action trajectory shapes that are constructed separately.

This explanation demonstrates that, contrary to the current state of science, the explanatory model shows that the perception processes within any conceivable motor action originate much more from a single universal source and illustrates that in all actions, an intersection point c.q. contact point between the animal and the environmental object must first be realized, and that after this contact, a pressing or pushing process usually follows. The model shows that the perceptual processes involved in the contact process when grasping objects are identical to the perception processes when pressing a button (e.g., piano key, touchscreen, elevator buttons, electric stove, light switch, etc.), pushing away a billiard ball, or kicking a football towards a goal. The contact process is perceptually identical in all cases. When grasping a coffee cup, however, a pressing or pushing process must follow the contact process within the relevant fingertips, resulting in a total zero vector. Conversely, pressing a piano key requires the creation of an actual movement vector to press the key down. The same applies to the other mentioned buttons and so the contact process within the free throw in basketball involves the same perception processes as in ordinary grasping.

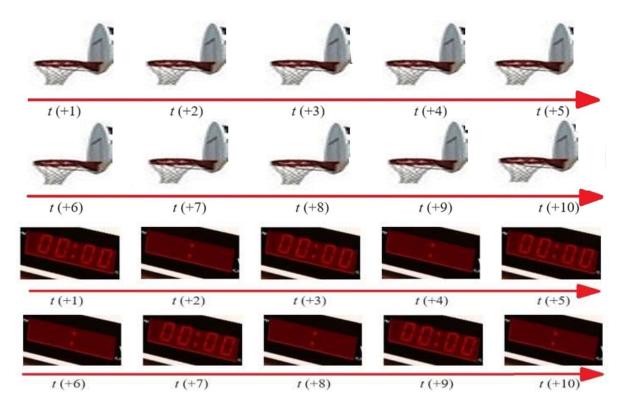

This overview document specifically addresses those aspects of the throwing and catching action within the free throw in basketball that are barely recognized within science. A small part focuses on

¹ Two important remarks: 1. Of course it is very important within evolutionary development of the perception processes that you can distinguish a lion from a zebra., and 2. Even till this day our visual perception processes observe the (external) movement of our body parts in the exact same way as they observe the movement of any other (external moving) environmental object. Solely due to internal perception processes in relationship to a causal connection with this external movement provides us the difference between the two.

² In part 1 (page 3), the explanatory model of the motoric movement action demonstrates that perception always observes stationary objects moving in time, but through an active comparison process can conclude that the object in question is stationary. Therefore, even though it is concluded that the coffee cup is stationary, zero-movement is indeed observed on a timeline, which can create an intersection point with an egocentric action trajectory shape in relationship to the grasping hand.

the perception of the basket within the catching action, but the vast majority of new insights are revealed concerning the egocentric throwing action that specifically focuses on the movement of the basketball. It shows the scientific evidence that 1. a perceptual image of a latent action trajectory shape from the basketball towards the basket is always created first, and 2. how this action trajectory shape can only be filled with the help of two autonomous foci. This overview document now summarizes all phenomena ever found within the movement sciences and forges them into one universal explanatory model. Based on logic, it can be concluded that this forms the complete and definitive explanation of all functional perceptual processes all throwing actions.

<u>Introduction</u>

In the dynamic world of visual perception and theoretical physics, seemingly simple objects like a stationary basket and a digital clock reveal surprising insights. This article explores how our visual system always perceives all environmental objects moving in time but can interpret them as static objects. By examining examples such as the blinking zeros of a digital clock and the static edges of a basket, we discover that our brains perform complex computations to understand stability and motion. The major ecological breakthrough encompasses the fact that stationary environmental objects are perceived in an identical manner to moving objects within the vista. These discoveries have profound implications, not only for visual cognition but also for our understanding of space and time, as outlined in Einstein's theory of relativity. This introduction invites you to explore the fascinating cross-pollination of psychology and physics, where the boundaries between perception and reality blur.

The Example of the Digital Clock

Consider the example of a digital clock where the zeros flash after a power outage. When the clock starts working again, the zeros blink on and off in exactly the same place. This example illustrates an important principle. The visual perception of the first set of zeros has no relationship with the later perception of the zeros, except for their identical position. This phenomenon illustrates how we perceive zero-movement in timeline segment shapes. Stillness can only be perceived through the active comparison of all observations over time, which allows us to deduce that stationary environmental objects within a vista are perceived as actively as moving environmental objects.

Perception of a Stationary Basket

We perceive a stationary basket in an identical manner to the flashing zeros on a digital clock. The basket's edges and contours do not change position over time. This lack of movement signals to our brain that the basket is stationary. Just as with the zeros on the clock, the perception of the basket at any given moment t(x) in time has no direct relationship with the perception of the basket at subsequent moments t(x+n) in time. Each moment is perceived independently, yet the consistency of the basket's position reinforces the perception of stillness.

- 1. Static Line Segments:
 - The static nature of the edges and contours of the basket creates a visual perception of stillness. These features remain in the same position, indicating zero movement.
- 2. Positional Data Consistency:
 - Each point on the basket's surface is linked to its previous and subsequent positions in time. This consistent positional data ensures that the basket appears stationary, as there is no disruption in its positional continuity.
- 3. Perceptual Continuity:

 Our visual system continuously processes these stable elements, reinforcing the perception of the basket as stationary. This perpetual perception is key to understanding how we interpret zero-movement within zero-movement line segment shapes.

Ecological and Visual Perception

According to Gibson's theory of affordances, the physical properties of our environment provide opportunities for action and perception. Our visual system has evolved to take advantage of these affordances. Light and moving space are intrinsic parts of our surroundings, and organisms have ecologically and organically developed mechanisms to interact according to these elements. The key idea is that every environmental object's actual position P(0) at time t(0) within a vista is connected to its manifest positions P(-x) at time t(-x) and future (latent) positions P(+x) at time t(+x), and thus is always confined within a line segment shape c.q. always is confined within a timeline. This continuity helps us perceive objects as stable and unchanging when they are at rest.

The Visual System as a Comparing Organ

Our perception system functions as a comparing organ, utilizing logic to interpret and understand our environment. Here's how this works:

1. Comparison Over Time:

Our visual system compares the positions of objects at different moments in time. For example, when looking at a stationary basket or the zeros on a digital clock, our brain continuously compares their positions at t(0), t(+1), t(+2) etc., in time. Despite perceiving each moment independently, the consistent positional data across these moments leads to the interpretation of stability and zero movement.

2. Logical Consistency:

The brain uses logic to make sense of the visual information. If an object appears in the same place repeatedly without any perceived movement between these instances, the brain logically concludes that the object is stationary. This logical processing allows us to understand and navigate a complex environment.

3. Pattern Recognition:

 Our visual system is adept at recognizing patterns and regularities. By comparing the spatial and temporal patterns of objects, it can determine whether something is moving or still. This pattern recognition relies on logical assessment of the consistency and changes in the visual input.

Zero-Movement within Action Trajectory Shapes

The concept of zero-movement within action trajectory shapes can be further illustrated through the perception of a stationary basket. Similar to the flashing zeros on a digital clock, the basket is perceived as being at rest because each point on its surface is linked to its previous and subsequent positions in time. This creates a continuous action trajectory shape that indicates no movement. However, it's essential to note that while the basket appears motionless in space, the entire explanation hinges on its movement in time.

Relationship with Relativity Theory

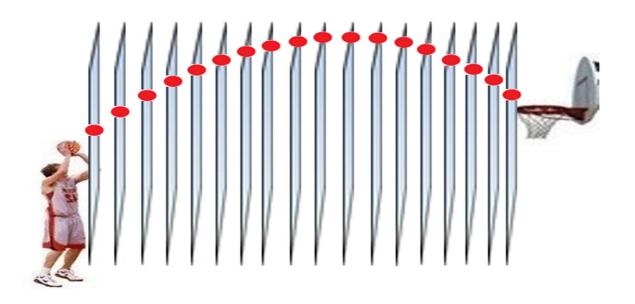

In the context of relativity theory, particularly as articulated by Einstein, the distinction between space and time becomes crucial. Objects can remain spatially stationary (zero-movement) while still undergoing temporal changes. This concept aligns with our perception of the basket: although it occupies a fixed spatial position, its temporal trajectory is dynamic. The basket's state evolves through time, even though it remains static in its spatial coordinates.

This interpretation resonates with Einstein's insight that space and time are interwoven into a single continuum, where objects move through both dimensions simultaneously. The perception of the basket's zero-movement line segment shapes reflects our visual system's ability to discern spatial stability amidst temporal progression. This dual perspective underscores the intricacies of perception and the deeper philosophical implications of how we understand movement and stillness in the universe.

Summary

The perception of a stationary basket and the zero-movement within a timeline illustrates a fundamental aspect of both visual perception and theoretical physics. While the basket appears static, acknowledging its temporal evolution highlights the complexity of our continuous active perception processes. This duality not only enhances our understanding of visual cognition but also deepens our appreciation for the interconnected nature of space and time, as explained by the theory of relativity.

Part 2 - Within the free throw we always first construct a perceptual image of a latent action trajectory shape out of the perspective of the basketball – The scientific evidence

Caught In A Line
The explanatory model of all motoric movement actions

N.J. Mol May 2024 ©

Introduction

The explanatory model of the motoric movement action provides a universal explanation of all functional perception processes within all goal-directed actions. It demonstrates that performing any conceivable action always requires the simultaneous perception of three autonomous foci³, in accordance with J.J. Gibson's theory, which includes both the movement of the animal/organism and the movement of the environment. When executing the free throw in basketball, one autonomous focus remains engaged with (the movement of) the basket as the environmental object, universally representing a catching action. The other two autonomous foci are concerned with the perception of movement within the egocentrically executed action, i.e., the movement of the basketball along an action trajectory shape (toward the basket), which universally represents a throwing action.

This article specifically focuses on the two foci belonging to the egocentric throwing action of the basketball in relation to the free throw in basketball. The explanatory model shows that every conceivable throwing action requires a compelling cooperation between an autonomous internal focus and an autonomous external focus. This insight, that two autonomous foci are present instead of a single undivided motor action, not only allows a final and ending specification of all individual perception processes but also reveals as a novelty that a coupling within the egocentric throwing action itself is capable to occur⁴.

The explanatory model of the motoric movement action thus provides a complete description of the *tau*-coupling process, wherein the essence of the task, the primary focus, is executed through (the perception of) the movement of the basketball over a pre-planned action trajectory shape between the current position of the ball and the basket⁵. This perceptual image is therefore determined in advance within a tactical consideration and involves identifying the future sequential positions the basketball must occupy to achieve a successful action. Sequential positions of any object effectively always create line segment shapes, and when the action is actually executed, the current position of the basketball is going to fill in that perceptual image step by step. Thus, it can be observed within a line segment shape that the *gap* of the latent positions P gradually disappears and, in full accordance with the findings of D.N. Lee, produces the *tau*-value, which plays a crucial role in the completion of the motor action in cooperation with the secondary focus⁶.

The explanatory model of the motoric movement action partly relies on logical reasoning but also presents scientific evidence. This chapter provides scientific proof that within the free throw in basketball, we always first create a perceptual image of a latent successful action trajectory shape before we actually perform any action.

³ The cortical streams mediate the grasping of a cup equal as they mediate within the nerve spiral (youtube.com) https://www.youtube.com/watch?v=QP4vPVAw-Yg

⁴ D.N. Lee did indeed identify the *tau*-value associated with the primary focus, but he considered the egocentric action as one indivisible whole. His lifelong quest to find the phenomenon it should be connected to remained unsatisfied because he never realized that the coupling occurs within the egocentric action itself.

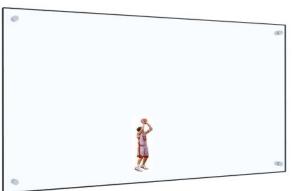

⁵ https://www.researchgate.net/publication/376723068 The free throw in basketball - Scientific evidence that random motor activity implicitly leads to the factual occurrence of an internal and an external focus and how their dominancy can be reversed

⁶ https://www.researchgate.net/publication/376032837 Within the free throw in basket-ball the ball moves within an external action trajectory shape and dictates all internal sensorimotor perception processes The tau-coupling process shows that we absolut

The scientific evidence

The evidence is very straightforward. You can verify it yourself through an empirical study where you are the test subject or you ask a test subject to execute classic free throws in basketball. The only instruction given is to only execute the free throw if the test subject believes there is a realistic possibility of actually getting the ball into the basket.

Images: The scientific proof is based upon the competence to visualize a giant huge glass shopping window. The left image shows a normal dimension of such a window. In relationship to the scientific proof you need to magnify that image 10 to 20 times. Like in the right image.

Choose a random basketball court with a random placed basket and create the following circumstances:

Situation 1: Do not alter the environment (zero measurement). Let the test subject execute classic free throws under normal circumstances.

Situation 2: Place a giant huge glass shopping window (height 20 meter x width 30 meter) between the basketball and the basket, close to the ball.

Situation 3: Place a giant huge glass shopping window (height 20 meter x width 30 meter) between the basketball and the basket, close to the basket.

Situation 4: Place a giant huge glass shopping window (height 20 meter x width 30 meter) between the basketball and the basket, at any random position P.

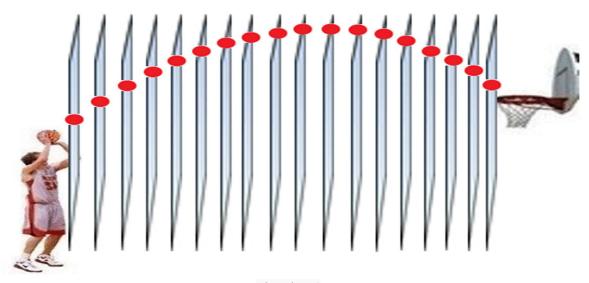

Images: In situation 1 a test subject will normally execute free throws. In situations 2 and 3, where a giant glass storefront is placed between the basketball and the basket, the test subject will not start a throwing action with the intent to actually score. This is because there is *one* (!) position P that is perceived as blocking the basketball.

Conclusion:

In situation 1, you and/or the test subject will just execute common free throws. In situations 2, 3, and 4, you and/or the test subject do not initiate a throwing action with the intent to let the basketball end up in the basket. Situations 2 and 3 do not provide significant insight on their own, but situation 4 clarifies everything. Whether the giant glass shop window is placed near the basketball or near the basket

makes no difference to the test subject. If there is a large shop window anywhere clearly present, the test subject will not initiate a throwing action with the intention to make a score. This applies to every conceivable position P of the shop window, from the very first position P(0) near the basketball to a shop window occupying the last position P(n) just before the basket.

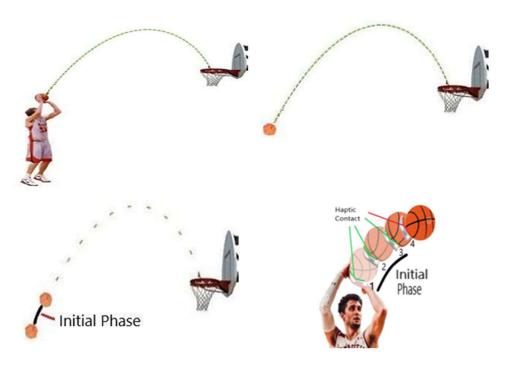

Situation 4

Image: In situation 4, it becomes clear that prior to the actual execution, we consider all consecutive *future* (!) positions of the basketball. It doesn't matter where the shop window is positioned between the ball and the basket; the action is not performed. Mathematically, one can argue that an uninterrupted series of consecutive positions P creates a line segment or line segment shape (action trajectory shape). The image provides a perfect visual representation that within a throwing action, we first form a perceptual image of the entire latent action trajectory shape before we actually execute anything.

This means that we assess every position P(0-n) between the basketball and the basket beforehand, clearly determining whether each position P allows the basketball to pass through so that it can ultimately reach the basket. In relationship to which it can be observed that if one position P is not *empty* (!), the mission is aborted. Upon which you can draw the factual conclusion that we will have to look at (!) c.q. we will have to perceive every position P(x) between the ball and the basket beforehand if that specific position P(x) is also allowing the physical dimensions of the basketball to pass. Mathematically, an uninterrupted series of consecutive positions P(x) can be designated as a line or line segment shape (action trajectory shape). This completes the scientific proof that within a throwing action, we first form a perceptual image of the entire latent action trajectory shape before we actually execute anything.

Part 3 - The execution of a free throw in basketball requires a mandatory coupling of an internal (secondary) focus and an external (primary) focus - The explanation of all functional perception processes within all throwing actions

Caught In A Line
The explanatory model of all motoric movement actions

https://www.researchgate.net/profile/Nj-Mol/research

https://www.explanatorymodel.nl/

Introduction

Traditionally, science has assumed that one motor action encompasses one focus. This assumption has seemingly been so logical that it has never been questioned. However, this has led to the absence of a plausible explanation for the functional perception processes underlying the execution of all motor actions, even after 100+ years of movement sciences. In 2016, an explanatory model was found that is capable of identifying all functional perception processes within any imaginable motor action. Beyond any reasonable doubt it conversely demonstrates that every motor action can only be executed through a compulsory coupling of two foci: an internal (secondary) focus must always be directed at an external (primary) focus. In which it should be explicitly noted that these two foci represent entities that fundamentally differ from current scientific terminology.

The explanatory model emphasizes that the essence of a motor task always involves the movement of an action object outside our body along an action trajectory shape, but that the action object will never be capable to move on its own along that line. The action object is often an inanimate object (pen, spoon, needle, key, tennis racket, ball, letter, pointer (pc) etc.) that we hold during an action, and even though the fingertips, during a grasp action with the hand on the outside, consist of living cells, we absolutely aren't capable of moving them there over an action trajectory shape on the outside of our body. The explanatory model unequivocally shows that initiating the movement of an action object along an action trajectory shape outside our body is only possible by using secondary perception of autonomous movements within our body.

Compared to the current state of science, the explanatory model represents a revolutionary break through, revealing that two foci must enter into an obligatory connection simultaneously, and this universal stacking of two perceptions of two autonomous movements occurs in every motoric movement action. They are clearly autonomous because they belong to two incompatible worlds. Observations of movement inside and outside the body are actually never able to overlap.

This article focuses entirely on the free throw in basketball. It presents compelling evidence that only the ball c.q. the movements of the ball itself, akin to a marble in a marble run, executes this action trajectory shape, thus accomplishing the task's essence. For this reason, primary attention must be directed towards the external movement of the ball. The ball can only be set in motion by entirely different movements within the body that only extend to the outer surface of the ball. The attention re quired for this must serve the main objective, hence referred to as the secondary (internal) focus. Furthermore, the explanation shows that all conceivable motor actions are based on these same two foci. Due to this universal nature, the explanatory model creates the most ultimate conceivable ecological argument. The article does not delve deeply into the differences with the current state of science because there is still no clear consensus on this subject within the scientific community.

The primary focus within throwing encompasses the perception of movement outside the body

The egocentrically formulated intention during a free throw is to get the basketball into the basket. The explanatory model of all motor movement actions demonstrates that solely the ball, or rather, the movements of the sole ball, will execute the essence of that task and thus constitutes the primary focus within this action, and in addition the explanatory model provides scientific evidence⁷ that any motoric movement action comprises two subsequent autonomous phases. In the first, a tactical consideration aims to establish a perceptual image of a latent action trajectory shape in which, in this case, the ball c.g. the movements of the ball will most likely succeed. Only then does one proceed to the factual execution of the action. So when we subsequently are going to carry out the action, we fill in that perceptual image of the latent action trajectory shape with the basketball. Therefore, within the primary focus, this is the essential process our perception processes must guide, a process that science has entirely overlooked thus far. Subsequent articles will reveal that filling in the action trajectory shape by the ball yields the crucial tau-value to which the secondary focus is compellingly linked and will be explained how the cortical streams mediate this process.

Images: The execution of a free throw solely encompasses the relocating of the basketball into the basket. The essence of this task is exclusively carried out by the autonomous movements of the ball, making it the primary process we need to observe. In this process, the ball follows an action trajectory shape akin the movement of a marble within a marble run. In any imaginable motoric movement action, the current position of the marble c.q. the action object will serve as the precise demarcation between the manifest and latent parts within the action trajectory shape.

Maybe we do construct perfect straight action trajectories when we create (latent) perceptual images of the future positions of the ball when we execute a free throw in basketball. However, due to the fact that you can only execute the movement of the ball with the perception of an entirely different autonomous movement, the ball will inevitably deviate from that "perfect" original pre-perceptual image at every position P within the action trajectory. This process is, therefore, guided by the double and mutual process of the cortical streams, representing the brilliant ecological response of the body to exe cute every motor action in the most efficient and effective way possible. The ventral and dorsal streams continuously interact with each other to correct the inevitable deviations, but this interaction does require a (very short) reaction time⁸. As a result we can never perform one motor action identical

https://www.researchgate.net/publication/371912704 The scientific proof that we primarily start with the construction of a perceptual image of an outgoing ball trajectory shape prior to the factual execution - The complete explanation of the free thro

⁸ The specific reaction time concerning cortical streams in relation to the explanatory model has never been examined. General information and empirical experiences provide an indication that the reaction time is estimated to be around 0.1 seconds; "It takes about one-tenth of a second for information about the visual scene to reach the back of the brain or the occipital lobes. During the next tenth of a second, the visual information is analysed in two separate ways. Figure 2 shows the two pathways of the dorsal stream and the ventral stream. The dorsal stream runs from the occipital lobes to three locations, the back of the brain at the top (called the posterior parietal lobes), a vertical strip of brain in the centre (called the motor cortex) and the front of the brain (called the frontal cortex). The ventral stream runs from the occipital lobes to the back of the brain at the bottom (called the

ly (conform Bernstein) and the basketball will always follow a different zigzag pattern while executing a free throw. Upon which the explanatory model hastily emphasizes that achieving an identical execution of motor actions has never been the objective of parsimonious organisms and therefor doesn't fit into an ecological evolution. Generating form similarity is far more efficient and effective.

Images: The explanatory model of all motoric movement actions has demonstrated beyond any rea sonable doubt that we effectively cannot throw a ball into a basket⁹. In a tactical phase preceding the actual execution, we can only reduce a perceptual image of an whole (latent) action trajectory shape between the ball and the basket to an initial phase where there is haptic contact between the hand and the ball. The explanatory model regards this as an undeniable fact.

The secondary focus within throwing encompasses the perception of movement inside the body

When one starts to realize that the primary focus solely concerns the movements of the ball, it implicitly becomes evident that the ball itself isn't capable to move at all. This analogy is strikingly similar to various other inanimate objects like tennis rackets, cricket bats, spoons, knives, bottles, pointers (pc) and more, which clearly never move on their own. But even when we grasp a coffee cup with our hand, the explanatory model demonstrates that the hand, and consequently the relevant fingertips, must also be considered as lifeless action objects. The outer layer of the fingertips does comprise living cells, but it is absolutely incapable of moving the fingertips in an action trajectory shape outside the body with those living cells. We can only induce movement in the outer layer of the fingertips through internal body movements. While they may approach the outer surface of the fingertips, they will always remain within the confines of the body. In the case of a free throw in basketball, this concept needs to be translated to the outer surface of the ball. We can only haptically perceive the ball with (the outer surface of) the hand and can only proprioceptively4 perceive how movements within our body influence the haptic contact between the hand and the ball.

The movement of the ball on the outside of our body can only be achieved by a system of movements on the inside of our body. The explanatory model defines the entire system of movements required for the displacement of the ball as a technique model and notes that performing a free throw involves a simple technical model. However, despite this realization, it remains a complex constellation of multi ple types of movements where no superior technical model can be identified. In a classical execution of a free throw, it can only be observed that there is leg, torso, arm, hand (palm), and fingertip action involved. It can actually be determined that you have never executed a single free throw with an

-

temporal lobes)": Cerebral Visual Impairment - Working Within and Around the Limitations of Vision; Gordon N Dutton; http://www.liv.ac.uk/~pcknox/Publications/trimble/CVI%20chapter%20for_hers-Dutton.pdf
https://www.researchgate.net/publication/372335518 You Can%27t Throw a Ball into a Basket You Can Solely Manipulate the Ball during Haptic Contact - Novel Insights within Free Throws and all Throwing Actions

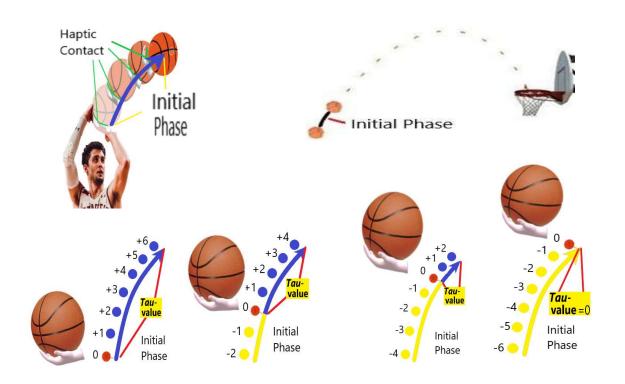

identical constellation of movements, and even if you were to try, you couldn't because the complex components within the technical model cannot be controlled or executed5 identically.

Images: In the case of the free throw, there is no apparent superior technical model6. In a classic execution of a free throw, it can only be determined that there is foot, leg, torso, arm, hand (palm), and fingertip action involved within a complex dynamic system. In which you can only remark that you have never executed a single free throw with an identical constellation of movements.

In many motoric movement actions, we do not consciously become aware of the existence of two foci, as they often involve straightforward observations. However, during a free throw in basketball, you can indeed learn to distinguish between the internal and external focus and experience them in the appropriate interconnected manner.

Part 4 - Within the free throw the essence of the task is solely carried out by the movements of the basketball; Within the primary focus the movement of the basketball produces the *tau*-value

Caught In A Line
The explanatory model of all motoric movement actions

N.J. Mol September 2023 ©

Introduction

Traditionally, science has assumed that one motor action corresponds to one focus. This assumption was likely so intuitive that it was never challenged. However, this has led to the situation where, even after more than 100 years of movement sciences, a plausible explanation for the underlying functional perception processes guiding the execution of all motor actions had never been found.

In contrast, in 2016, an explanatory model emerged that has the capability to identify all functional perception processes within any imaginable motor action in a universal way. It demonstrates, beyond any reasonable doubt, that each motor action can only be executed through a mandatory coupling of two foci: an internal (secondary) focus that must always be directed towards an external (primary) focus. In which it should be explicitly noted that these two foci represent entities that fundamentally differ from current scientific terminology.

Regarding the external (primary) focus, it can be observed that science has so far missed truly everything. Therefore, it will now be comprehensively discussed within a wide spectrum of motor actions, and this publication now reveals all aspects of the primary focus within the free throw in basketball. Within this publication, it is explained that one can't factually throw a ball into a basket. You can only construct a perceptual image of a whole (successful) latent outgoing ball trajectory shape, limited to solely that part of the ball's trajectory when actual haptic contact occurs between the ball and the hand. The explanatory model defines this as the initial phase. In this epistle it will be explained that the external (primary) focus encompasses the perception of the phase in which there is actual haptic contact between the hand and the ball, and although this seems like a very brief time frame, it will become clear that the movement of the basketball solely within this initial phase produces the essential *tau*-value. Which must be linked to the internal (secondary) focus through a strict *tau*-coupling process.

Solely the movements of the basketball encompass the essence of the task c.q. the external (primary) focus

The category of motor actions discussed by the explanatory model pertains the conscious actions where it is assumed that there is always an initial formulation of an egocentric intent (an egocentric formulated will). So before picking up a coffee cup, for instance, there is always the desire to do so. The explanatory model of all motoric movement actions recognizes this as an undisputed factual

aspect but adds a caveat. The egocentrically formulated intent does not, for example, concern picking up the coffee cup itself. The explanatory model reveals that this is factually incorrect and that we can only move our fingertips toward the coffee cup. Therefore, the movement of the fingertips toward the coffee cup constitutes the essence of that action. In the present action, we might indeed be very eager to satisfy our hunger, but the egocentrically formulated goal pertains solely to moving the spoon to the plate and/or to the mouth. Only that aspect thus determines the essence of the task, and therefore, only that aspect should be regarded as the external (primary) focus.

So within the free throw in basketball we obviously aim for a high score but the egocentrically formulated goal pertains solely to guiding the ball through the initial phase correctly. It is factually impossible to execute more than that and, therefore, only this element should be considered as the external (primary) focus.

The tactical movement action (TMA) within the free throw in basketball

Images: First, we establish the egocentric intent to accurately guide a basketball into a hoop. Then, from the current position of the ball, we construct a perceptual image of a complete latent outgoing ball trajectory shape (OBT) between the ball and the hoop, which might be successful, and condense this whole shape to solely an initial phase, as this is where we can actually influence the ball's path. This occurs as part of a tactical action in which two important goals are considered. Firstly, it must lead to a successful action, and secondly, ecologically evolved organisms aim to perform actions as parsimonious as possible. The explanatory model of the motoric movement action provides scientific evidence¹⁰ that, while we do register possible obstacles in the environment, visual perception is primarily focused on creating an action trajectory shape that forms a completely interconnected line of positions P for the basketball. Although it may appear that without obstacles, we wouldn't construct a perceptual image of a latent action trajectory, because there seemingly are no obstacles, this is entirely incorrect. We primarily perceive the positions P where there is nothing to see c.q. which don't contain any obstructing matter. This, in essence, defines the tactical action, even when there seemingly are no physical obstacles on the future (action) path of the ball.

The explanatory model of the motoric movement action demonstrates that after formulating an egocentric goal, we always engage in a tactical consideration, prior to any execution, to determine how we can bring the action object to the goal location within successive positions P. In the context of the discussed action, we always create a perceptual image of a latent action trajectory shape, allowing the ball to be moved successfully toward the basket.

¹⁰ https://www.researchgate.net/publication/371912704 The scientific proof that we primarily start with the construction of a perceptual image of an outgoing ball trajectory shape prior to the factual execution - The complete explanation of the free thr. Additionally the scientific evidence has been unequivocally provided for all grasping actions and all throwing actions, and can be easily universally extrapolated to any conceivable action. N.J. Mol; Grasping encompasses two consecutive autonomous phases - The scientific proof that we tactically construct an action trajectory shape prior to the factual execution of that exact same action trajectory shape.

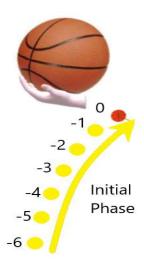

Images: It is not straightforward to present an animation that accurately represents the latent action trajectory shape being constructed. The image on the left very clearly displays the shape of the trajectory, in which all contiguous points P are distinctly weighed. However, it does not illustrate that within the construction of the trajectory shape, all dimensions of the basketball are also precisely incorporated, as shown in the image on the right. The perceptual image we pre-construct of the trajectory might possibly contain a hybrid blend of these two animations.

The factual movement action (FMA) within the free throw in basketball

After determining a perceptual image of the initial phase of the latent outgoing ball trajectory shape, we proceed to actually carry out the action. This process effectively starts with bridging the gap from the current position of the basketball P(0) to the next position P(+1) within the action trajectory. Although our ultimate intention of course is to reach the end of the initial phase to actually release the basketball, the explanatory model clearly illustrates that during this phase, our perception processes are solely concerned with bridging the empty space between the beginning and the end of that initial phase. Which at a micro-level shows, that essentially only the positions P(-1), P(0), and P(+1) matter to us during this bridging process.

Images: In an animation, the progression within the initial phase can be depicted as follows. Within any conceivable action, the action object can successfully execute the action only by first occupying the next position P(+1) within the action trajectory. The current position P(0) then shifts one step forward, and a manifest position P(-1) is added. This process repeats with every new position P(0) until the end of the action trajectory is reached. To comprehend the perception processes at the most fundamental level it is of the utmost importance that you start to understand that the latent part of the initial phase will factually need to sprout out of the already manifest positions P(-x).

The perception-action coupling within the free throw in basketball

With the preceding argumentation, the explanatory model of the motoric movement action now provides a comprehensive and universal explanation of how perception is linked to the action within any conceivable task. The animations in the previous section illustrate that the action object maintains a fixed relationship with the perceptual image of the action trajectory shape. This becomes easier to comprehend when envisioning a marble in a marble run. In this analogy, you will become much more aware that the perception-action coupling is a unified phenomenon where only a single change occurs every ongoing time span. Within the marble run it becomes quite visible that during the actual execution, each position P(0) serves as the precise separation between all already manifested positions P(-x) and the latent positions P(+x) yet to be traversed.

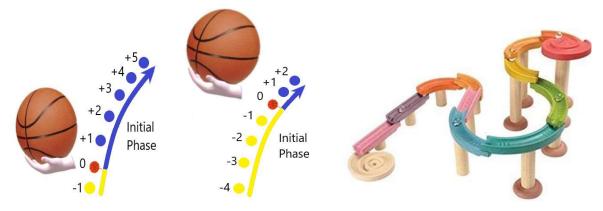

Through this explanation of the perception-action coupling, the explanatory model can precisely demonstrate how organisms must have evolved within an ecological framework. However, delving into this subject exceeds the scope of this publication. Instead, several crucial points will be highlighted concerning the functional perceptual processes within this motor action.

It's imperative to recognize that while the ultimate goal is to reach the end of the initial phase within the free throw, during the execution of this action, we are solely engaged in bridging the basketball through empty space where seemingly nothing is happening. It can be observed within any conceivable action that we spend relatively more time bridging this nothingness than in actual observable activity. The explanatory model, however, unequivocally shows that not only the end goal matters, but all positions P between the beginning and the end of the initial phase are equally significant.

Additionally, it must be remarked that the action of the ball at P(0) can be perceived distinctly, yet no fixed unit of time can be attributed to it. Each unit of time can be divided into a thousand smaller units.

fixed unit of time can be attributed to it. Each unit of time can be divided into a thousand smaller units, and these units can be further subdivided, leading the explanatory model to argue that the action at P(0) fundamentally takes such a brief time span that it only gains significance in relationship to perceptions of the adjacent time frames. In other words, perceiving the current position of the basketball solely gains meaning through the adjacent future "actual" positions P(+x) and the adjacent manifest

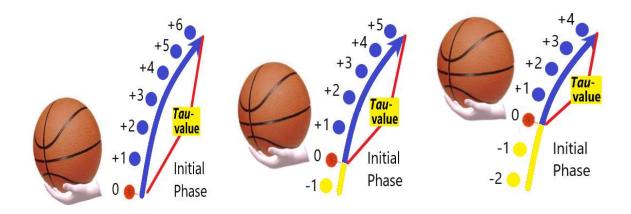

"actual" positions P(-x) of the ball. Within which the overarching idea is to emphasize that perceptions within any conceivable action mainly pertain to one single phenomenon wherein the perception of the action also compels a perceptual image, but primarily that they are absolutely interdependent.

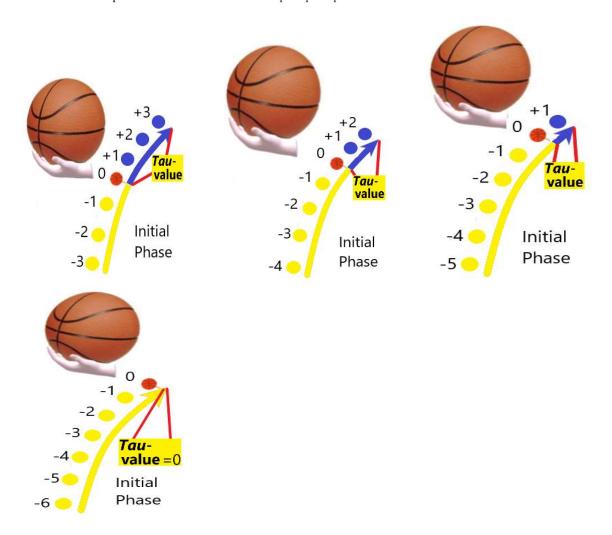

Images: Within many motoric actions the action trajectory shape will not become visible, making it challenging to depict with animations. Conversely, the marble within the marble run, is capable to vividly illustrate this concept. It clearly showcases one single phenomenon wherein the marble, at each position P, delineates the precise separation between all already manifested positions P(-x) and all latent positions P(+x). Additionally, it exemplifies one of the essences of the coupling. If we couldn't perceive the marble run, the movements of the marble would lack essential context, and conversely, without the marble, we would be completely unable to perceive any coupling as well. There is a compelling interdependent relationship, and without that coupling, we would never, under any circumstances, be able to execute any motoric movement action.

The tau-value within the free throw in basketball

The explanatory model of the motoric movement action demonstrates with the aforementioned perception-action coupling that the perception of each position of the basketball c.q. the action object within the initial phase is equally important. However, as the ball approaches the end of the initial phase of the outgoing ball trajectory shape, the task c.q. the egocentrically formulated goal starts to become finalized. Within any imaginable motor action, the action object will universally traverse the action trajectory shape until there are no latent positions P left. Within his *tau*-coupling theory, D.N. Lee referred to this phenomenon as the closing of the gap c.q. as the *tau*-value approaching to zero.

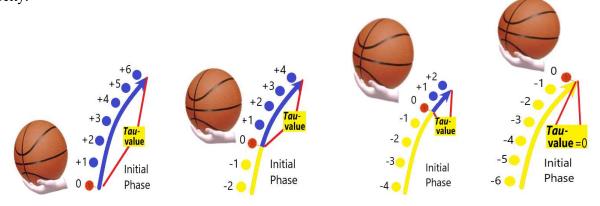

Images: Within the perception-action coupling, the basketball will traverse all latent positions P that are tactically predetermined within a perceptual image of the initial phase of the whole outgoing ball trajectory shape. With each successive position P of the ball, the *tau*-value will decrease, until it eventually approaches zero c.q. becomes zero.

The perception of the tau-value within the free throw in basketball

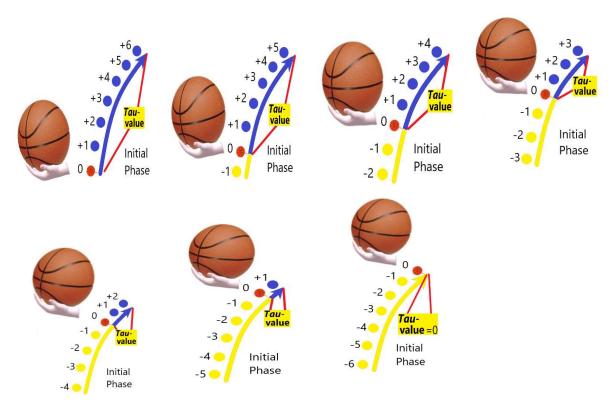

Observing the *tau*-value within the external (primary) focus is an essential process because, within a strict *tau*-coupling, it must establish a compelling relationship with the internal (secondary) focus to make an action successful. When it is perceived that the basketball is approaching the end of the initial phase, the perception within the internal focus must ensure that the bodily movements reaching up to the ball are adjusted in such a way that the ball is released precisely on time and with the correct velocity.

Images: The *tau*-value can be perceived in two autonomous ways. You can either observe how the yellow manifest action trajectory shape takes over the blue line or at the most basal level you could solely observe with what speed the blue line, representing the still latent action trajectory shape, is disappearing. Within which you factually solely observe how the latent (blue) gap is closing.

Perceiving the *tau*-value approaching to zero can be observed in two autonomous ways. The first way involves filling in the perceptual representation of the entire latent action trajectory shape with the manifest positions P of the basketball. In animations, this should be depicted as the yellow line taking over or filling in the blue line. The other way involves a much more fundamental way of perceiving the *tau*-value. In contrast to the first way, this is solely based on the disappearance of the latent positions P from the perceptual representation of the entire latent action trajectory shape. Which means that you solely observe with what speed the blue line c.q. the gap disappears.

Part 5 - Within the free throw in basketball the ball moves within an external action trajectory shape and dictates all internal sensorimotor perception processes; The *tau*-coupling process shows that we absolutely don't need a motor plan

Caught In A Line
The explanatory model of all motoric movement actions

N.J. Mol November 2023 ©

Introduction

When we want to execute a successful free throw in basketball, the explanatory model of the motoric movement action has demonstrated that only the movement of the ball embodies the core of the task and thus the essence of our egocentric intention. In which scientific evidence has been provided that, prior to the actual execution of any conceivable action, we first create a perceptual image of an entire latent action trajectory shape along which we can successfully move all dimensions of the action object¹¹, in this case, the ball, towards the basket¹².

However, science has so far completely missed all the essentials regarding the action trajectory shape and only indirectly noticed that (action) paths are formed between the end effectors c.q. the action object, and the goal of the action. While it can be quickly established that all positions P of an action object are invariably constrained within one single line segment shape within any conceivable motor action. This should have led to several revolutionary insights:

- 1. Factually, the action object invariably fills an action trajectory shape in the same way as a marble moves within a marble run, in which the perception of the marble's current location always marks the exact boundary between the manifest and latent parts of the perceptual image of the action trajectory shape.
- 2. All latent positions P of the action object effectively always have to sprout from the manifest positions P, or effectively always have to originate from the manifest part of the action trajectory shape.
- 3. Within the action trajectory shape, it factually always becomes apparent when the action is coming to its end due to the perception of the disappearing of the complete latent action trajectory shape c.q. the tau-value approaching to zero¹³.

However, although the explanatory model demonstrates that the perception of the movement of the action object within the perceptual image of a latent action trajectory shape encompasses an autonomous phenomenon and thus exclusively is going to perform the essence of the task, the explanatory model also clearly shows that the action object itself absolutely isn't capable to move on its own. Even

¹¹ Science and the explanatory model of the motoric movement action use the terms 1. end effector and 2. action object for the same phenomenon. For example, in eating with a spoon, science refers to the spoon bowl as the end effector, whereas the explanatory model designates the spoon bowl as the action object. The action object in pouring is the liquid level, and this may feel somewhat peculiar. Nevertheless, this is the aspect we focus on during pouring, and which has been demonstrated within scientific research (Hayhoe, Land e.a.).

https://www.researchgate.net/publication/371912704 The scientific proof that we primarily start with the construction of a perceptual image of an outgoing ball trajectory shape prior to the factual execution - The complete explanation of the free thr

¹³ https://www.researchgate.net/publication/374255784 Within letter posting the essence of the task is solely carried out by the movements of the letter Within the primary focus the letter moves like a marble in a marble run producing the tau-value

when grasping with the fingertips, the explanatory model shows that the movement of the fingertips along an external action trajectory shape on the outside of the body can't be moved by the outside of the fingertips themselves. So even within grasping, the movement within the external (primary) focus can only be executed with movements that must always be perceived within the body, within the internal (secondary) focus. In the current action, where a basketball moves far outside the body towards the basket, this insight will be easily recognized and one can easily determine that the ball can only be moved over an external action trajectory shape with movements within the body that only reach up to the outer surface of the ball^{14,15}.

Images: The explanatory model of the motoric movement action indicates, beyond any reasonable doubt, that no motor plan is required to carry out an action. It demonstrates that all sensorimotor perception processes within the internal (secondary) focus simply need to follow the lead of the external (primary) focus. This clarification, which does not require any hierarchy, underscores our freedom from being tied to specific sensorimotor movements and this perspective is in perfect alignment with an ecological approach to motor actions. In the case of a free throw, it is a fact that you solely have haptic contact with the ball during the initial phase¹⁶. Therefore, before the actual execution of the free throw, you need to reduce a perceptual image of an entire successful action trajectory shape to that unique beginning. Only that part can be performed, and thus, the *tau*-coupling process takes place only in that part.

In summary, this leads to the conclusion that the phenomenon of the perception-action coupling is solely related to the perception of movement within the external (primary) focus. Only within this focus, a perceptual image, consisting of the future positions P of the action object, is filled by the future (actual) positions of that exact same action object. Also, only within this focus, the *tau*-value can be perceived. This publication now explains how the perception of the *tau*-value should be linked to the internal (secondary) focus and extensively discusses the consequences this has for the perception processes within the internal (secondary) focus c.g. for all sensorimotor actions.

A universal tau-coupling is present within every conceivable motoric action

¹⁴ https://www.researchgate.net/publication/373139666 The execution of a free throw in basketball requires a mandatory coupling of an internal secondary focus and an external primary focus - The explanation of all functional perception processes within a

¹⁵ This intriguing dualism demands our utmost attention as it presents the essence of our perception processes. The internal (secondary) focus not only meticulously tracks the movement of the action object within the action trajectory shape but is also the instigator of this movement. It might sound paradoxical that the very action you initiate creates your own reliance. However, this is precisely what occurs because it is an implicit fact that when you move something inside your body, an external part of your body will inevitably move within an action trajectory shape on the outside of your body.

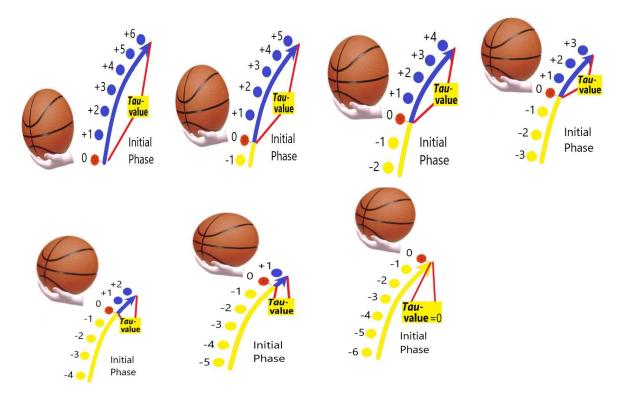

¹⁶ https://www.researchgate.net/publication/370978349 Gaze and the visual perception of the basket are two totally separated phenomena within the free throw in basketball - The exact origin of gaze within all sports actions compels the stacking of two pe

The explanatory model, in conjunction with previous publications, demonstrates that the *tau*-value can be universally observed within any conceivable action. This aligns with the findings of D.N. Lee, who showed that in many actions, a gap c.q. a line segment shape between the action object and the end goal¹⁷ gradually approached zero and eventually completely disappeared. While Lee's discovery generated significant interest in the scientific community, a major breakthrough remained elusive. Lee connected this crucial *tau*-value to various irrelevant other possible *tau*-values without realizing that multiple foci could be distinguished and linked within a single motoric action.

However, this insight proved to be highly relevant for the explanatory model of the motoric movement action. By understanding that the movement of an action object along an action trajectory shape outside the body is a completely autonomously observable phenomenon and can only be executed by a completely different autonomously observable phenomenon within the body, it is now possible to explain precisely which phenomena should be connected and how the *tau*-coupling is established. The perception of the *tau*-value approaching zero within the external (primary) focus should ultimately guide the observations within the internal (secondary) focus.

The tau-coupling when executing a free throw in basketball

Prior to actually throwing a basketball towards a hoop, a perceptual image is always created of an entire latent action trajectory shape, over which all dimensions of the ball will eventually be successful. You can ascertain that it is a fact that we can only manipulate the ball when there is haptic contact between the ball and the hand, and therefore it is obligatory to reduce the entire latent outgoing ball trajectory shape to a perceptual image of an initial phase c.q. we need to simplify the entire path into a perceptual image of how the outgoing ball trajectory shape commences. The execution of the initial phase covers the whole motoric action. So, once we have thrown the ball the entire action is completed because our hand is no longer in contact with it.

Images: Solely the ball will construct the initial phase of the entire action trajectory shape, and thus,

¹⁷ In the original work, examples include a long jumper leaping towards the take-off bar, a Northern Gannet diving toward the water surface, and a bee heading towards a flower.

only the ball carries out the essence of the task. It can be observed that the ball moves like a marble in a marble run, and the actual position P(0) of the ball (red) always marks the precise separation between the manifest (yellow) and latent (blue) parts. The disappearance of the latent part of the action trajectory shape can be perceived in two ways. One can observe how the yellow (manifest) part takes over the blue (latent) part of the action line, or more fundamentally, one can solely perceive at what speed the blue line segment disappears.

While it may appear that only the end of the action trajectory is crucial, the explanatory model is clear: the bridging process of every position P of the ball within the initial phase is equally vital for success. The finalization of the action and the bridging process are, in fact, two distinct phenomena that must be successfully executed sequentially. One can never reach a successful conclusion if the bridging phase has not been successful as well.

However, the successful completion of the end is also crucial to make an action succeed, and it stands or falls with perceiving that the *tau*-value, within the external (primary) focus, approaches zero. Then, within the internal (secondary) focus, adjustments in motor movements needs to be conveyed to the outer surface of the ball, so that the ball is precisely pushed by all fingertips simultaneously at the end of the perceptual image of the initial phase¹⁸.

The perception processes regarding the motoric movements on the inside of the body within the internal (secondary) focus while manipulating the outside of the basketball

The explanatory model of the motoric movement action presents a completely new paradigm. It's built on the factual observation that an autonomous internal movement of any organism will implicitly lead to an autonomous external movement of the outside of that organism. In which it is also a fundamental fact that the movement of any given position P on the outside of that organism will need to sprout out of each other c.q. that all those positions P will always be interconnected. Which factually means that they will always create a line segment shape. So, the most important conclusion reveals that these two movements are implicitly connected, but that the perception processes mediating these movements are completely autonomous and independent of each other¹⁹.

This aforementioned clarification doesn't pertain to the paradigm itself but to its foundation. In regard to which the explanatory model notes that these phenomena occur regardless of which focus you centralize. However, the new paradigm lies in the novelty that you can fully execute a motor action by focusing solely on creating and completing an external action trajectory shape. In contrast to the idea that early organisms primarily started by emphasizing arbitrary motor movements within the body and

¹⁸ The explanatory model underpins the notion that within many motoric actions a bell-shaped profile is capable to occur when plotting the execution speed of an action against time in a graph. In many actions, it is indeed typical that after a short initiation phase, a smooth and faster bridging phase occurs, followed by a more precise phase towards the end. Although the model generally supports these principles, it doubts the emergence of a highly proportional bell shape in all cases. Additionally, the explanatory model illustrates that this is certainly not the case for all actions. In situations where you need to create a crescendo at the end of the action, such as clapping your hands or defending against an attacker with a punch or a kick, you must accelerate the relevant body parts in the final phase. Similarly, in many ball sports, achieving a necessary "crescendo" can only be accomplished if, after an initial relatively slower catching phase, you maximize acceleration of the ball towards the end of the action trajectory shape. Which can also be noted within the free throw in basketball.

¹⁹ While the explanatory model of the motoric movement action has a strong suspicion that the earliest organisms initially engaged in random motor movements, it demonstrates that after millions of years of evolution, the roles of internal and external have reversed. It's much more efficient for organisms to work from an action trajectory shape rather than relying on random motor movements. Creating an action trajectory shape, for instance, from fingertips to a coffee cup or from a spoon to a soup bowl, is by far more effective and efficient than repeatedly generating random internal movements with the hope that the fingertips will reach the coffee cup or the spoon will reach the soup.

then observing the external result, the explanatory model states that these roles have now been completely reversed after millions of years of evolution. So, within the free throw in basketball, we primarily perceive the dominant movement of the entire ball within the external (primary) focus and guide its progress with motoric movements within the internal (secondary) focus, which, within the body (!), only reach toward the outer surface of the ball.

Thanks to this new paradigm, the explanatory model of the motoric movement action is now capable of identifying all functional perception processes within any conceivable motoric action, thus enabling it to describe all sensorimotor perception processes within any conceivable motoric action. In this section, a list of the most crucial insights will be outlined, with a focus on challenging many prevailing assumptions within the scientific community.

a. Visuomotoric perception processes

Of course, science views both visual perception and motor action as essential in executing actions, assuming they share a close relationship. Which, out of a single-focus perspective, led to the rather artificial birth of the term *visuomotoric* perception processes. While one might argue that the term provided some direction in scientific thinking, its content remained vague and never led to any significant consensus.

The explanatory model now emphatically reveals that this term represents an erroneous way of thinking within the scientific community and that it must be expunged from the realm of scientific discourse. The explanatory model effectively illustrates that, in practice, when visual perception comes into play, its exclusive role is to contribute to the perception-action coupling taking place within the external (primary) focus and has no bearing whatsoever within the internal (secondary) focus. In plain terms, visual perception, by itself, will never induce any movement.

b. Sensorimotoric perception processes

Just like the concept of visuomotoric perception processes, science introduced the term *sensorimotoric* perception processes. In contrast to the previous paragraph, the explanatory model provides a significantly broader description in regard to those sensorimotoric processes than previously presumed in the scientific community and shows unequivocally that we even can execute motoric actions solely through proprioceptive perception, expanding our capabilities beyond what science has traditionally acknowledged. Many actions can be executed with ease, albeit less efficiently, in complete darkness or without any visual input^{20,21}. Consider activities like clapping your hands behind your back, unlocking a door with a key at night, or swatting an annoying mosquito behind your ear. In all these actions, the *tau*-value within the external (primary) focus can be entirely perceived proprioceptively²². Additionally, the explanatory model unmistakably reveals that within any conceivable action, an external (primary) focus, operating within a strict *tau*-coupling process, can only be executed by an internal

²⁰ Motoric displacement actions from point A to point B, such as walking, cycling, rowing or car driving, can hardly be executed without visual input. However, a person with 100% visual impairment is perfectly capable to navigate through their home freely and by foot travel significant distances outside using a cane. This cane vividly demonstrates that our perception processes are not solely focused on reaching point B but are also deeply engaged in the bridging process. With the cane, the individual is essentially "observing" (feeling) whether the next position P (+1) within the perceptual image of the latent action trajectory shape, is accessible and can be occupied by their body. This observation mirrors what was mentioned earlier regarding the spoon's journey towards the mouth or towards the plate of soup.

²¹ Think also of inserting a car key into the ignition. In an unfamiliar car, we need visual perception several times initially to create an action trajectory shape, but after a few repetitions, we do it entirely blindly.

²² https://www.researchgate.net/publication/342715828 The complete functional explanation of limb position and movement in relationship to the proprioceptive perception - The behavioural perception processes within clapping behind your back

(secondary) focus. It highlights that this secondary focus is exclusively perceived within the body, and therefore, all perceptions within this focus are inherently of a sensorimotoric nature.

c. The internal (secondary) focus has an indispensable interdependent relationship with the external (primary) focus.

So, the explanatory model revolves around an entirely new paradigm, which reveals that within the execution of a single action, implicitly two autonomous foci arise in relation to two autonomous movements. These two autonomous foci must enter into a mandatory collaboration to accomplish the action successfully. The collaboration involves the motor processes within the internal (secondary) focus, which alone can enable the action object to move, compellingly following the movement within the external (primary) focus. When one is first confronted with this concept, it may evoke an extremely paradoxical feeling. How can a phenomenon that is inherently essential to the action and only solely can ensure the action's success be so dependent on another autonomous phenomenon that it itself brings to life? However, with further contemplation, one will come to realize that it is a remarkable evolutionary discovery and that it provides an explanation for all functional perception processes within any conceivable motor action. Moreover, the explanatory model clearly elucidates how this phenomenon must have developed from the earliest stages of evolution, but further details are omitted here for the sake of brevity²³. It is emphasized that these two phenomena are entirely interdependent, and without either one, no motor action can be successfully executed.

d. No motor plan and no hierarchy

If the scientific community were to acknowledge that the perception of the movement of an action object within an action trajectory shape, within the external (primary) focus, has the capability to guide the entire execution of any conceivable motoric action, several challenges within science would be resolved immediately. If it were accepted that, prior to the execution of a motor action, we create an allencompassing and directing perceptual image of an external latent action trajectory shape, the need for a motor plan would instantly disappear. Which would lead to the understanding that all sensorimotor movements simply serve the external (primary) focus, and as a result, there would be no need to recognize hierarchy within the sensorimotor structure. Then all sensorimotor activity can hierarchically be regarded at the exact same level which just obediently have to carry out the task within the external (primary) focus.

e. The explanatory model reflects an optimal ecological approach

In the current scientific paradigm, there is a consensus that motor planning exists, but there is absolutely no agreement on how such a motor plan is developed. While it's acknowledged that creating a motor plan demands more cognitive capacity from an organism, it essentially reveals that, even after many decades, there is no clear answer to this question. An important, unanswered scientific question is how a motor plan adapts when a sudden change occurs during an action. Which also leads to the pressing follow-up question of how more primitive organisms can cope with such situations.

²³ In future publications, where the precise role of the cortical streams in regard to this phenomenon will be explained, this evolutionary development will be further elucidated. In brief, the explanation will demonstrate that organisms initially started with just random (!) movements within their bodies to move a part of the external body somewhere. After millions of years, we 1. realized that this specific external body part, like a marble in a marble run, fills an external action trajectory shape, and 2. gained a solid understanding of the involved motoric movements. This understanding allowed us to reverse the roles, shifting from initiating movements from inside the body to initiating them from the outside. This line of thinking even goes so far as to suggest that the cortical streams within an organism have evolved evolutionarily to precisely mediate this relationship of a marble-marble run in a double and reciprocal process.

The explanatory model of the motoric movement action demonstrates that perceiving the *tau*-value, despite its inherent complexity, can be distilled into a very simple universal phenomenon. Which is also explained in the context of the free throw in basketball²⁴. To perceive the *tau*-value, all you need to do is register the speed at which the latent part of the perceptual image of the initial phase of the entire action trajectory shape disappears. Essentially, this amounts to a straightforward observation of the disappearance of a two-dimensional line segment.

Subsequently the explanatory model reveals that the internal (secondary) focus can align itself with the external (primary) focus as a whole, without any rigid hierarchy. This simplifies the observation of the *tau*-coupling process to such an extent that, within an ecological framework, it's hard to surpass and which concept can also be applied to the earliest organisms.

f. The motoric movements toward the outer surface of the basketball are proprioceptively perceived

The explanatory model clearly demonstrates that the internal (secondary) focus is exclusively perceived within the body, highlighting that there is no involvement of visual perception in this process. The internal (secondary) focus can only be proprioceptively perceived. You can actually verify this during the execution of a free throw by first creating a perceptual image of an initial phase of an outgoing ball trajectory shape with the help of visual perception and then execute the free throw with your eyes closed²⁵. It may feel somewhat strange, but it won't affect the throwing action.

g. Hybrid (proprioceptive) perception processes

A significant shortcoming in scientific research pertains to the notion that motor actions are always executed with roughly the same sensorimotor perception processes. The explanatory model reveals a universal framework, but it clearly demonstrates as a novelty that often multiple constellations of perception processes are involved within the execution of the same motoric action and that we are capable to endlessly, *ecologically* (!), vary within this realm.

For example, when in pitch black darkness, we bring our (non-key-holding) hand to a lock, we can successfully move the key to the lock using solely proprioceptive perception within the external (primary) focus c.q. we can successfully move the key along a perceptual image of a latent action trajectory shape using solely proprioceptive perception processes. So even if it then appears that we perform this motoric action with only visual perception in broad daylight, that's factually incorrect. The visual perception will be very dominant, but proprioceptive perception will naturally always remain in a hybrid form. In the classically performed free throw, visual perception will also be present within the external (primary) focus, but we always carry out the action proprioceptively. Therefore, besides visually observing the ball going to the basket, we always *feel* (!) the construction process of the initial phase of the outgoing ball trajectory shape.

Within the internal (secondary) focus, it is no different. You can quickly realize that you can make the basketball move with various types of body actions (leg, torso, arm, hand/palm, and fingertip actions). The product of all these actions shows such a clearly complex whole that it will not be further elaborated upon here.

²⁵ Michael Jordan executes free throws with his eyes closed: <u>Michael Jordan - Eyes Closed Free Throw Compilation! - YouTube</u>. LeBron James executes a backward free throw: <u>LeBron James Backwards Free Throw - YouTube</u>.

²⁴ https://www.researchgate.net/publication/374380188 Within the free throw the essence of the task is solely carried out by the movements of the basketball Within the primary focus the movement of the basketball produces the tau-value

Images: The explanatory model defines the entire assembly of movements required for the displacement of the ball as a technique model, noting that executing a free throw is a simple technique model. However, despite this observation, it remains a complex constellation of multiple types of movements. In a classic execution of a free throw, it can be noted that leg, torso, arm, hand (palm), and fingertip actions are involved in regard to which we can practically establish that you have never executed or could execute a single free throw with an identical constellation of movements. Due to the fact that the complex components within the technique model can never be controlled or executed identically.

So, you might have developed your own preferred motor skills within the free throw in basketball, but they will always consist of an ever-evolving combination of hybrid sensorimotor perceptions. Due to the fact that such a complex phenomenon is involved will never allow an identical configuration of perception processes to arise. Upon which the explanatory model of all motoric movement actions again hastily wants to add that these hybrid possibilities in the utmost harmony align within an ecological approach and that a parsimonious organism would never have strived to achieve identical executions and will never strive to do so.

h. Optimization process

The explanatory model of the motoric movement action demonstrates that a motoric action can only be executed by the stacking of two autonomous foci and shows within the previous paragraph that the perception of movement within the internal (secondary) focus is inherently of such a high complex nature that it will definitely prevent the occurrence of an identical internal configuration to occur. Consequently this will cause that the action object is capable to and definitely shall deviate from the perceptual image of the latent action trajectory shape at each progressing point P and even though the cortical streams ingeniously mediate this process, it's empirically evident that an identical execution of any action trajectory shape is unattainable. This unequivocally portrays that performing any conceivable action can only be viewed as an optimization process. Hence, you will never be able to make a ball move identically. Instead, you solely can optimize the perceptions within both foci, which also allows you to perform actions in a very successful manner but in ever-varying ways.

i. Within the internal (secondary) focus the line and shape within the line segment shape of the action trajectory demand autonomous perception processes; Solely the line generates the *tau*-value

The explanatory model of the motoric movement action demonstrates, beyond any reasonable doubt, that we do not (need to) create motor plans and that all sensorimotor processes can be compellingly guided by the external (primary) focus. But if a motor plan would have been necessary, science would still have remained remote from a breakthrough, as sensorimotor processes must accompany two autonomous phenomena within the action trajectory shape that have never been recognized in science. The frequently used compound term "action trajectory shape" is in fact a line segment shape and encompasses two autonomous components: the line and the shape. The explanatory model illustrates that they are perceived entirely separately but simultaneously. For experts, this is clearly recognizable

within any conceivable action. However to make it comprehensible for everyone, these phenomena are explained within the context of the motoric movement action *car driving* (or riding a bicycle) since this action inherently contains the scientific evidence of these two autonomous perceptions.

Images: In the case of a car and a bicycle without hand brakes, only the steering wheel can compensate for deviations in the width of the action trajectory shape, and the pedals can only compensate for deviations in the length of the action trajectory shape.

When driving a car, it becomes immediately evident that one can exclusively influence the movement within the shape (!) of the action trajectory with the steering wheel. This defines the explanatory model as mediating the deviations in the y-axis. Additionally, it should also become immediately clear that with the pedals, one can exclusively influence the movement within the line (!) of the action trajectory. This defines the explanatory model as mediating the deviations in the x-axis²⁶.

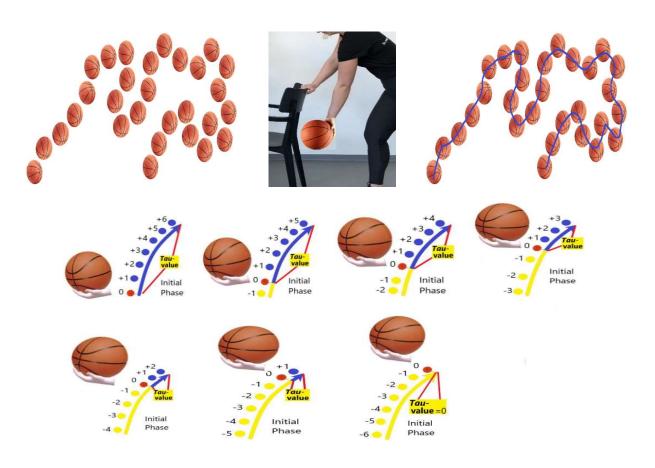

So, when driving a car, it becomes crystal clear that perceiving (and controlling) the shape has absolutely nothing to do with perceiving (and controlling) the line. In which it is essential to mention that perceiving the filling of the latent line (within the x-axis) by the manifest places P of the action object within the external (primary) focus solely involves the *tau*-value which within car driving is solely executed by the pedals. Solely the speed with which the line is filled determines the duration of the action c.q. determines the finalization of the action.

The explanatory model of the motoric movement action demonstrates that the perception of movement within the internal (secondary) focus in any conceivable action, including the current free throw action, contains the same x- and y-axis components. Although it places greater demands on the development of an organism, conversely, it can be shown to fit perfectly within an ecological approach. The dichotomy, where a separate x- and y-axis component is distinguished, can actually deliver the final breakthrough in the understanding of why we are capable to reduce very complex perception processes to the perception of such trivial and simple phenomena. The mere perception of the x-axis can be traced back to simply perceiving how the latent part of the perceptual image of the latent action trajectory disappears.

-

²⁶ The same explanation naturally applies when considering a bicycle with coaster brakes.

Part 6 - The free throw in basketball — Scientific evidence that random motor activity implicitly leads to the factual occurrence of an internal and an external focus and how their dominancy can be reversed

Caught In A Line
The explanatory model of all motoric movement actions

N.J. Mol December 2023

Introduction

The explanatory model of the motoric movement action is capable of delineating all functional perception processes within any conceivable action. Nevertheless, challenges are encountered in its implementation within the scientific community due to the intrinsic nature of a new paradigm within a complex dynamic system. The explanatory model demands the simultaneous integration of multiple innovative mind steps.

In order to facilitate those necessary subsequent steps in science, a series of new articles is introduced, each time focusing on a different motoric action which will be assessed within the complete spectrum of (general) motor activity. The aim is to provide a broader perspective on specific motor activity required for goal-directed actions. Additionally, they universally demonstrate that motor activity always leads to the simultaneous autonomous perception of both internal and external movements, which can be appointed as primary or secondary, and finally, they elucidate all elements underlying the explanatory model of the motoric movement action.

This article centers around the essential task of the free throw in basketball. The explanation consists of three parts. The first part exclusively focuses on general motor activity and not on specific actions. Here, an action is defined as deliberate motor activity aimed at performing a specific task as a result of an egocentrically formulated intention. At the end of this part, the free throw is fully explained in relation to general motor activity. In contrast to the first part, the second part addresses deliberate c.q. specific goal-directed actions where an egocentrically intention is formulated to actually throw a ball into a basket. Two action strategies are highlighted in this part, logically stemming from the general motor activity mentioned in the first part. The concluding part emphasizes the relationship between the discussed motor activities and the explanatory model of the motoric movement action.

Part 1 - Internal motor (movement) activity when no deliberate goal-directed action is involved

The explanatory model of the motoric movement action identifies all functional perception processes within any conceivable action. In which the fundamental assumption encompasses that the action arises from explicitly formulating a particular egocentric will. However, in this paragraph, we do not assess a specific motor action with an egocentric intention yet. In here we solely focus on general

motor activity. The distinction between mere motor activity and conscious actions provides valuable insight into the broad spectrum of motor (movement) activity.

a. Basic exercise (passive arm without a spoon)

The entire explanation is built upon a basic exercise, involving a forward-leaning posture with one arm hanging passively downward. This posture is often used in physiotherapy exercises to allow isolated movement of the arm. That is strenuously not the intention of this exercise. It is essential to keep the arm entirely passive during the execution of the basic exercise.

Images: The basic exercise illustrates a forward-leaning position with a passive arm. Despite the apparent action in the images, the primary goal is to develop and observe other body actions and notice how they laterally influence the movement of the passive arm.

Although the hanging arm is prominently present, you are now asked not to focus on it specifically. Conversely, the emphasis must be put on developing other than arm activities (knee, torso, head, foot action, etc.) and observing whether the passive arm is going to move.

Conclusion of the basic exercise (passive arm without a spoon)

It can be conclusively observed that you are capable to (secondarily) perceive movement of all separate positions P of the outside of a passive arm by directing (primary) attention to an entirely different internal motor activity. This observation carries the following factual conclusions:

- 1) While there is nothing predictable about where the passive arm will move, as random internal motor activity will always result in random or chance movements of the passive arm, there is, on the other hand, a very essential fact to note. All individual points/positions P of the arm will always have to be connected c.q. will always have to emerge from each other. If we, for example, were to focus on three points of the arm, such as the fingertips, knuckles of the fist, and the elbow²⁷, you cannot escape the factual conclusion that all those points always move in a line segment shape and that it always involves only one (!) line segment shape²⁸. So, this applies to all places on the arm, and within there it can also factually be established that each position P of the arm will move like a marble in a marble run²⁹. The current position P (0) of each piece of the arm will always mark the separation between the manifest positions P (-x) and the future positions P (+x).
- 2) The second very essential conclusion encompasses the fact that the two movements have a causal connection, but the perception of the movement of internal motor activity (knee, torso, head, foot

²⁷ Hence, you must also realize that when grasping a coffee cup, where we typically focus on the movement of the fingertips, all other mentioned body parts also move in linear forms. This demonstrates that the related perception processes are entirely subjective and depend on the chosen focus.

²⁸ Indeed, you can factually ascertain that your own body, from birth to the end of life, is also confined within one extensive line segment shape. Your body at every position P(0) is, in fact, bound to the penultimate position P(-1) and the subsequent position P(+1). There is simply no escaping it. You are factually "Caught In A Line".

²⁹ https://www.researchgate.net/publication/336880958 The explanatory model of all motoric movement actions - The Marble Run

action, etc.) has absolutely nothing to do with the perception of the movement within the linear form where all separate parts of the arm become part of so.

b. Basic exercise (passive arm with a spoon)

A crucial aspect of the preceding conclusion involves the fact that internal sensorimotoric movements implicitly lead to a movement of, for example, the fingertips over an external line segment shape outside the body. There is, therefore, a direct causal relationship between these two movements, with the remarkable phenomenon that, without internal motor activity, an action trajectory shape of the fingertips is just not capable to occur. However, it is essential to establish that the perception of the movement of the fingertips over an action trajectory shape outside the body, in spite of this crucial causal relationship, has no connection with the perception of internal sensorimotoric movements. To further clarify this intriguing duality, the basic exercise is repeated, with the sole difference that the hand of the passive arm is holding a spoon. The entire exercise proceeds identically to the description above.

Images: In the repetition of the basic exercise, only a spoon is added, while the exercise remains unchanged. It is crucial, once again, not to develop conscious arm action but merely to observe how other bodily actions influence the entirely passive arm with the spoon. Now you can factually establish that all separate positions P of the arm but also all separate positions of the spoon will start to move in line segment shapes. Due to the fact that all those separate positions can only emerge from each other c.q. they will always be interconnected.

Conclusion of the basic exercise (passive arm with a spoon)

Like in the first version of the basic exercise it can be factually established that you are capable to (secondarily) perceive movement of all separate positions P of the outside of a passive arm, now holding a spoon, by directing (primary) attention to an entirely different internal motor activity. This observation carries the following factual conclusions:

1) While there is nothing predictable about where the passive arm with the spoon will move, as random internal motor activity will always result in random or chance movements of the passive arm with the spoon, there is, on the other hand, a very essential fact to note. All separate points/positions P of the arm and all separate points/positions P of the spoon will always have to be connected c.q. will always have to emerge from each other. Once again, the three previously mentioned arm positions (the fingertips, the knuckles of the fist, and the elbow) will create a line segment shape, but also all the separate positions of the spoon also form separate lines. If you focus, for example, on the handle or the bowl of the spoon, you cannot escape the factual conclusion that all those points always move in a linear form, and that, too, always involves exact one (!) entire line segment shape³¹. So, all separate positions of the arm and of the spoon are going to traverse a

³⁰ The explanatory model of the motoric movement action demonstrates in numerous articles that the two perceptions of two types of movements are autonomous because they belong to the incompatible worlds of inside and outside the body. Therefore, there can never be a blending of the two.

³¹ Hence, you must also realize that when eating soup, where we typically focus on the movement of the spoon-bowl, all other mentioned body and spoon parts also move in line segment shapes. This demonstrates that the related perception processes are entirely subjective and depend on the chosen focus.

- linear form and within there it can also factually be established that each position P of the arm and of the spoon will move like a marble in a marble run. The current position P(0) of each piece of the arm and spoon will always mark the separation between the manifest positions P(-x) and the future positions P(+x).
- 2) The second highly essential conclusion, as mentioned in the first version of the basic exercise, remains fully intact here as well. The perception of the movement of internal motor activity (knee, torso, head, foot action, etc.) has absolutely nothing to do with the observation of the line segment shape that all parts of the arm and now the spoon become a part of. However, the new aspect introduced by the spoon concerns the fact that a spoon is an inanimate object. What leads to the astonishing factual conclusion that, for instance, we can observe the movement of the spoon's bowl over a line, but we can only generate motor activity up to the outer surface of the handle of the spoon. The perplexing aspect of this realization may be the fact that the movement of the spoon's bowl over a line segment shape is entirely dependent on a completely different internal motoric movement. Without this source of action, the spoon's bowl will never move. Additionally, the confirming aspect of this realization may concern the conviction that the perception of the movement of the spoon's bowl over a line has absolutely no connection with the perception of internal motor movement activity.

c. The basic exercise in relation to motoric arm activity moving a ball

If we define an action as a conscious motor activity in which a specific goal is pursued from an egocentrically formulated will, then the explanation in the entire first part of this article falls outside the framework of actions. In this paragraph, we still do not assume a conscious goal-directed action, but rather build upon what the basic exercise regarding the movement of a spoon demonstrates.

Images: The basic exercise can be translated into moving a basketball. You should primarily focus on manipulating the outside of the ball c.q. you should mainly direct your proprioceptive perception towards the outside of the part of the ball where there is contact with the hand and only tangentially (secondarily) notice whether and how the (entire) ball moves through the air. Even if you engage only in upper arm, forearm, hand, or even just finger action, the consequences remain the same³².

As the previous paragraph illustrates, the basic exercise can easily be translated into an action involving an external (lifeless) object, such as a ball. To maximize the distinction between the (perception of) the movement of the spoon bowl/ball and the (perception of) the movement of internal motor activity, and thus make the principles easily accessible, you were specifically asked not to perform any arm activity. However, the distance between the spoon bowl/ball and internal motor activity doesn't matter

³² Two essential omissions should be noted in the animations: 1. Only a limited number of ball positions are represented. If you engage in a few minutes of random motor activity, the entire environment should be filled with ball positions. 2. The connection of successive positions P of the ball cannot be captured in an animation. The perception of the ball's movement involves a continuous (smooth) line of balls. The blue line represents this continuous connection but does not actually show balls. Therefore, you need to create a hybrid perceptual representation, which you can only really perceive by actually moving a ball in the air.

at all. Even if you focus primarily on (internal) motor arm activity, you can secondarily observe that the spoon bowl or the ball moves randomly through the air. You can develop only upper or lower arm activity, but even if you develop only hand or even solely finger action, the same principles will still apply. It should be reiterated that you can only empirically determine that the position P(0) of the ball, in the present action, must always result from the preceding positions, and that all positions P of a moving ball are always confined to one line segment shape.

Conclusion basic exercise in relation to motoric arm activity moving a ball

In actions involving lifeless objects, such as a ball, it becomes immediately clear that you (secondarily) can make the ball move by focusing entirely on a different (primary) motor activity, which can only reach up to the outer surface of the ball. This is the only thing necessary to draw the following factual conclusions:

- 1) Although there is nothing predictable about where the ball will move, as random internal motor activity will always result in random or chance movements of the ball, there is, on the other hand, a very essential fact to note. All separate points/positions P of the ball will always have to be connected c.q. will always have to emerge from each other. Due to which one can conclude that all those points always construct a linear form, and that, too, always involves exact one (!) entire line segment shape. The ball will move in that linear form in the same universal manner as a marble moves within a marble run. In which the current position P (0) of the ball will always serve as the precise separation between all manifest positions P (-x) and all future positions P (+x).
- 2) Once again, the second highly essential conclusion follows the explanation as in the case of the other basic exercises. The perception of the movement of internal motor activity has absolutely nothing to do with the perception of the movement of the ball within the line segment shape that all positions of the ball become a part of.
 The perplexing aspect of this realization may be the fact that the movement of the ball over a line segment shape is entirely dependent on a completely different internal motoric movement solely reaching the outer surface of the ball. Without this source of action, the ball will never move. Additionally, the confirming aspect of this realization may concern the conviction that the perception of the movement of the ball over a linear form has absolutely no connection with the perception of internal motor movement activity.

Part 2 - Internal motor (movement) activity when a deliberate goal-directed action is involved

The explanatory model of the motoric movement action encompasses the clarification of all functional perception processes within any conceivable action, assuming that these are conscious actions driven by an egocentrically formulated will, with a clearly defined specific goal. So, the motor movements in the first part specifically did not involve actions aimed at placing motor activity in a larger context. Conversely within the second part, general motor activity will now be translated towards specific motoric actions. Although the explanatory model of the motoric movement action is emphasized more in this part, the explanation within this section still aims to clarify the entire spectrum of motor (movement) activity.

So, within the second part we do assume deliberate goal-directed actions where an egocentric will is formulated to achieve a specific goal and in this chapter the free throw in basketball encompasses the main issue. The basic exercise clearly shows that two possible action strategies c.q. execution perspectives can be pursued in this regard.

a. Execution perspective 1 – Primary focus on the internal motor movements towards the outer surface of the ball and secondary focus on the external movement of the ball

The basic exercise from the first part clearly demonstrates that with primary attention on internal motor activity, focused on the exterior of the ball, we can randomly move the entire ball through the air. However, this random movement becomes problematic when formulating the egocentric intention to trace a precise path with the ball. With primary attention focused on internal motor activity, we can make the ball occupy a tremendous amount of space in the air in a matter of minutes, but it is far from

economical (efficient and effective) to create an initial phase of an outgoing ball trajectory shape in that way.

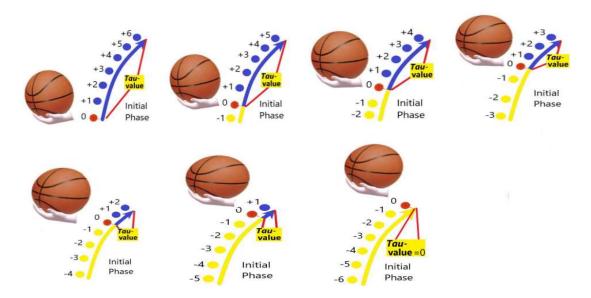

Images: Even when one wants to move a ball within a goal-directed action, it always remains a strategy to focus primarily on the outside of the ball, while secondarily observing whether the entire ball ever reaches a goal externally. Although it requires a lot of luck and/or patience, it is a possible action strategy. However, in every basketball throw, it will never lead to any success.

Factually you are solely capable to create an outgoing ball trajectory shape during the haptic contact between the ball and the hand c.q. you can only create an outgoing ball trajectory shape within the time span when contact with the ball is present. This is defined as the initial phase. So, a perceptual image of an entire latent (successful) outgoing ball trajectory shape must be reduced to that initial phase, and the ball must move within that initial phase in a very precise way and be launched at a very precise moment through precise timing of multiple fingertips. The first action strategy remains possible; however, for throwing tasks, it can never be a reasonable alternative. There are too many complex requirements that allow very little deviation within the fluctuation limits of the execution.

b. Execution perspective 2 – Primary focus on the external movement of the ball and secondary focus on the internal motor movements towards the outer surface of the ball

Contrary to the description of random motor activity within the basic exercises within the first part of this article and also in contrast to the previous action strategy, when it comes to the emergence of a deliberate action, one can adopt a completely different execution perspective. It would indeed be by far the most parsimonious (ecological) solution to first conceptualize an action trajectory shape between the ball and the basket and then proceed to execute it.

Images: The most parsimonious (efficient and effective) approach is to first construct a perceptual image of an initial phase of a complete latent outgoing ball trajectory shape over which the ball will successfully reach the basket and then proceed to factually execute it.

In the second execution strategy, the roles of attention are reversed. The primary focus now has the goal to track the progress of the ball within the initial phase of the outgoing ball trajectory shape, and this must be followed secondarily by motor activity. In which you now have to observe, similar to the basic exercise in the first part, that motor activity passively follows the primary focus. It would, of course, be by far the most parsimonious execution strategy, but the reversal of roles requires significantly more cognitive capacity. While the first execution perspective allows for a straightforward initiation of the action, the second one demands the following essential cognitive skills:

- a. It demands that first a perceptual image of a latent action trajectory shape is constructed over which the ball can be successfully moved towards a basket, and this must be reduced to a perceptual image of only the initial phase of that outgoing ball trajectory shape, within which haptic contact exists between the hand and the ball.
- b. A significant complex system needs to be present which must be capable of mediating the (perception of) the movement of the ball within the initial phase of the outgoing ball trajectory shape. While the roles of attention can be reversed, will not change the fact that the ball can only be moved by (the perception of) a completely different autonomous (internal) phenomenon. Even if we try to enforce that the ball actually fills in the perceptual image of the latent initial phase, the autonomy of the motor activity will cause the ball to deviate from that perceptual image at every position P.

Part 3 – General conclusion

The explanatory model of the motoric movement action is capable of appointing all functional perception processes within any conceivable action. However, its implementation in the scientific world encounters several challenges. It represents an entirely new paradigm and involves an explanation within a complex dynamic system where multiple new conceptual mind steps must be combined simultaneously. Therefor the goal is to try to enhance the insights around the explanatory model, and for that purpose, the preceding paragraphs zoomed in on the entire spectrum of motor activity. From a generally recognizable image, a translation was made to the core concepts and thought processes demanded by the explanatory model of the motoric movement action.

In the end, within this article, two possible action perspectives were identified based on general motor activity. Without any reasonable doubt it becomes clear that the second perspective, where the primary focus is pointed at the construction and execution of a perceptual image of a latent (external) action

trajectory shape, will be far more superior to the first mentioned action strategy. However, this ultimate parsimonious solution also reveals which additional conditions the most superior action strategy should meet:

- a. Firstly, an organism must have the cognitive ability to create a perceptual image of a latent action trajectory, over which, in the present action, the ball can be successfully moved towards a basket. Regarding this first condition, the explanatory model of the motoric movement action has provided universal scientific evidence that we create such a perceptual image within every conceivable action. This has been specifically addressed within computer³³, grasping³⁴ and throwing³⁵ tasks, but it can easily be adapted to any conceivable action.
- b. Secondly, an organism must have the cognitive ability to mediate the movement of the ball within the perceptual image of the initial phase of the outgoing ball trajectory shape. The mere quintessence of this article encompasses namely that motor activity is a completely autonomous phenomenon and although it has a direct causal relationship with the movement of the basketball within an action trajectory shape, the ball will never be able to move by itself. So, we might be intensely motivated to reverse the roles of the primary and secondary focus and envision very neat and smooth (optimally economical) outgoing ball trajectory shapes but due to the autonomy of the perception of both movements, we simply cannot execute them in that way. The autonomous perception of the external movement of the ball will eagerly try to follow the perceptual image of the latent outgoing ball trajectory shape, but the autonomous proprioceptive perception towards the outer surface of the ball will actually cause the ball to deviate at every position P within the perceptual image of the initial phase of the outgoing ball trajectory shape.

The explanatory model of the motoric movement action thus concludes that there must be a very heavy significant system to mediate the ever-deviating movements of the ball within an ever-deviating outgoing ball trajectory shape each consecutive time frame. Regarding this second condition the explanatory model finds that this very heavy system is present within the processing processes of the perception c.q. is present within the functioning of the cortical streams and, based upon current scientific literature, it asserts that there is a double and mutual relationship between the dorsal and ventral stream. In the present free throw task, the dorsal stream is mainly related to the processing of perceptions concerning the specific position of the basketball, and the ventral stream is mainly related to the processing of perceptions concerning the perceptual image of the initial phase. However, this must be seen as mutual. At any time frame *t* or at any point P (0) of the action, one perceives the ball relative to the action trajectory shape and vice versa. So, the dorsal stream mainly processes the position of the ball, but this is always related to the initial phase of the outgoing ball trajectory shape, and conversely, the ventral stream mainly processes the progression within the initial phase of the outgoing ball trajectory shape, but this is always related to the specific position of the ball

Caught In A Line
The explanatory model of all motoric movement actions

N.J. Mol May 2024

Introduction

The explanatory model of the motoric movement action provides a profound understanding of all functional c.q. behavioural perception processes occurring within any conceivable motoric action. Nonetheless, challenges arise in its implementation within the scientific community, given the intrinsic nature of a new paradigm within a complex dynamic system. It necessitates the simultaneous integration of several innovative mind steps, including:

- 1. The scientific evidence showing that, as part of a tactical (ecological) consideration, we always first create a perceptual image of a latent action trajectory shape before we actually start to throw a basketball towards a basket.
- 2. The understanding of the necessity of a compelling collaboration between an internal and an external focus in every motor action. The movement of the basketball in relationship to the external action trajectory shape, within throwing tasks, can solely be perceived outside the body and is only caused by perception of movements within the body, reaching only to the outer surface of the basketball. Due to their exclusive domains these perceptions are incompatible.
- 3. The assumption of the crucial role of the movement of the basketball over the action trajectory shape as the essence of this throwing task, wherein the external focus must be hierarchically considered primary. This assigns a secondary status to the internal focus and demonstrates that no motor plan is ever conducted.
- 4. The explanation of how the primary focus generates the *tau*-value and how the secondary focus needs to obediently follow the development of that *tau*-value within a strict *tau*-coupling process, providing the first ecological explanation for anticipating all unexpected events during an action.
- 5. The insight that when we move the basketball from point A to B, within the initial phase of an outgoing ball trajectory shape, it is a subjective choice from the perspective of the entire ball. With the same arm action, all other parts of the arm (elbow, hand, upper arm, etc.) also move in a unique action trajectory shape. This demonstrates that there is a causal relationship between the perception of internal and external movements when moving an arm with a ball, but an explicit relationship only arises when we subjectively "choose" the basketball as the action object.

As a concluding step, this chapter delves into the functioning of the cortical streams when we aim to throw a basketball in a basket. It provides a comprehensive understanding of why they must play such a pivotal role c.q. why they are ecologically/evolutionarily developed. Additionally, it is precisely explained how they mediate two autonomous processes within every motor action, namely the zigzag process and the accordion process³⁶.

1. The tactical movement action (TMA) within the free throw in basketball encompasses the construction of a perceptual image of a latent outgoing ball trajectory shape between the current position of the ball and the basket and to reduce it to the initial phase where haptic contact between the ball and hand occurs

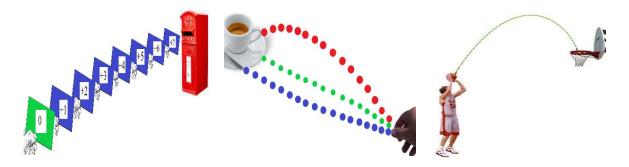

_

³⁶ In previous publications, this has been referred to as the harmonica process.

Supported by scientific evidence³⁷, the explanatory model delineates that the execution of any motor action involves two distinct sequential phases: the tactical movement action (TMA) and the actual movement action (AMA). The tactical movement action is focused solely on planning the upcoming action and must be finalized before any actual execution occurs. An essential aspect of the tactical movement action within a throwing task is to create a perceptual image of a latent action trajectory shape between the current position of the ball and the basket. Then it is equally essential to reduce this perceptual image to the phase of the intended outgoing ball trajectory shape, defined as the initial phase where haptic contact between the ball and hand exists c.q. the only timeframe in which we can egocentrically influence the ball.

The explanatory model demonstrates that during this phase, we are indeed largely focused on all physical dimensions of the basket aligning with much scientific research. However, with the recognition that a perceptual image of a latent action trajectory shape is being created, the explanatory model also arrives at a conclusion that is not yet recognized within the scientific community. The construction of a perceptual image of a latent action trajectory shape between the current position of the basketball and the basket also indicates that we strategically determine beforehand whether the space between the ball and the basket (in the very near future) can be filled or bridged by a continuous line segment shape of all dimensions of the basketball. The explanatory model provides irrefutable scientific evidence³⁸, and you can quickly conclude from your own empirical experiences that you create a completely different action trajectory shape when there are opponents in front of the basket, and that you do not create any perceptual image of an action trajectory shape when the basket is shielded by a huge shop window.

Images: Within letter posting and grasping we also construct a perceptual image of a latent action trajectory shape during the tactical movement action (TMA) like in any conceivable motoric action, over which *all dimensions* (!) of the action object (i.e., the letter and the fingertips) will enable the action to succeed. During the actual execution within the actual movement action (AMA), akin to the basketball, one must perceive the movement of the action object during the bridging process, as only the basketball, the letter, and the fingertips are going to move c.q. can be moved egocentrically. Within the

38 https://www.researchgate.net/publication/371912704 The scientific proof that we primarily start with the construction of a perceptual image of an outgoing ball trajectory shape prior to the factual execution - The complete explanation of the free thro

³⁷ https://www.researchgate.net/publication/372335518 You Can't Throw a Ball into a Basket You Can Solely Manipulate the Ball during Haptic Contact - Novel Insights within Free Throws and all Throwing Actions

images, it is particularly noticeable that we actively perceive whether the entire path through all dimensions of the fingertips, the basketball, or the letter can be filled in a continuous action trajectory shape c.q. we mainly perceive the "nothingness" in the vista in front of us. Because only in that void there is (empty) space to successfully execute an action.

In addition to unveiling this novelty, it is also revealed that our perceptual processes, after the tactical movement action, will primarily focus on executing the perceptual image of the initial phase, as the ball can only be influenced egocentrically during that phase. This contrasts with the traditional perspective of science, which remains constantly focused on the basket itself. So during the actual movement action (AMA), we are thus primarily engaged in the egocentric bridging process of the basketball within the initial phase c.q. in guiding the basketball according to the perceptual image of the beginning of the latent outgoing ball trajectory shape. So when the factual execution starts the basket itself is not any longer the focal point, but rather the movement of the basketball towards it c.q. the bridging of the void between (!) the current location of the ball and the basket forms the essence of the action. Another revolutionary novelty aligns with the previous thought. Although reaching the end of the action trajectory shape will eventually lead us to the completion of this task, the explanatory model, supported by scientific evidence, demonstrates that we also tactically determine beforehand whether the entire (!) space between the basketball and the basket can be filled by a continuous line segment shape of all dimensions of the basketball. This means that all positions P between the current location of the basketball and the basket are observed as actively and as crucially as the endpoint of the action trajectory shape. This realization provides a solid foundation for the fact that during the actual movement action (AMA), we are solely focused on traversing the latent positions P associated with the action trajectory shape. This implies that upon reaching position P(x), for example, somewhere midway along the action trajectory, we are mainly focused on the perception of three positions: position P(x-1), where we just came from, position P(x), where the ball is now, and position P(x+1), the perception of the next position where we need to move the basketball. In this phase, we are primarily engaged in the aforementioned bridging process and only monitor whether the gap between the basketball and the end of the initial phase icon is closing. This also reveals another essential ecological novelty, showing that during the actual movement action (AMA), we are indeed not concerned with the basket itself, but only with reducing the number of latent positions P within the initial phase of the outgoing ball trajectory shape.

2. The reciprocal dependency between the internal and external focus results in absolute deviations of the basketball within the perceptual image of the latent action trajectory shape

The explanatory model of the motoric movement action unequivocally illustrates within the context of throwing a basketball into a basket that two foci always arise³⁹. We can only guide the basketball along an external action trajectory (from A to B) with a focus on internal movements. These foci are autonomous because the (perception of) movements occur strictly separated inside and outside the body, rendering them incompatible.

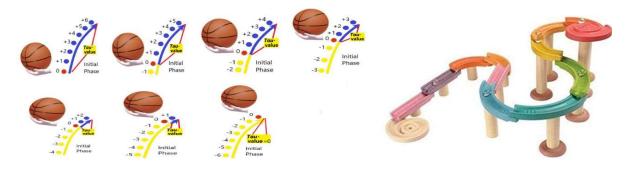

However, as the explanatory model now demonstrates that the movement of the basketball within the external action trajectory shape is going to fulfil the essence of the task, an intriguing phenomenon of reciprocal dependency emerges. Only internal motor movements towards the outer surface of the basketball can lead the basketball externally along an action trajectory shape, yet the progression of the ball within that trajectory will, as the primary focus, dictate those internal motoric movements. The inevitable consequence of this observation encompasses that it is not a matter of whether the basketball will deviate within the perceptual image of the latent initial phase of the outgoing ball trajectory

³⁹ https://www.researchgate.net/publication/373139666 The execution of a free throw in basketball requires a mandatory coupling of an internal secondary focus and an external primary focus - The explanation of all functional perception processes within a? sg%5B0%5D=r-H_vtLGKRrq70zRd6NHzsUpwvMuWuxJC3-rI2DafEgPlgR3JvSoKzHwM4mBUanTER6UG-bcVho7EkbCofT3Xx7Wma-BTAlkVaai4qu-V.ohtafGRQKKSH5cvL2bAs03cqvq2Ci3mWBsXtFDIIMHtV8Ox-cnGba4yjK-e7t3YNqTJnZU4RTi54cSyfrzX5ZRA&_tp=eyJjb250ZXh0Ijp7ImZpcnN0UGFnZSI6In-Byb2ZpbGUiLCJwYWdlIjoicHJvZmlsZSIsInBvc2l0aW9uIjoicGFnZUNvbnRlbnQifX0

shape, but rather that this is an absolute certainty. In which this absoluteness logically stems from the factual nature of the autonomous perception of both foci.

3. Within the actual movement action (AMA) the cortical streams will have to mediate the continuous flow of absolutely emerging deviations

If we now combine the two preceding paragraphs and proceed to actually throw the basketball towards the basket, our main endeavour will primarily become to initiate the bridging process of the basketball in which the perceptual image of the initial phase of the outgoing ball trajectory shape serves as an open yet compelling guiding⁴⁰ phenomenon. This means that we aim to *step by step* (!) reduce the distance between the current position of the basketball and the end of the initial phase, starting with the first step of moving the basketball from position P(0) to position P(+1).

Images: The explanatory model of the motoric movement action provides a tangible example with the marble in the marble run, illustrating the continuous reciprocal perception-action coupling within any conceivable motoric action. From the perspective of the marble's current position, one can perceive the relationship within the entire marble run, and vice versa, one can perceive the relationship with the marble's current position from the perspective of the entire marble run. Although all this remains invisible within throwing tasks, it is present in an equivalent manner. Because in our worldly dimensions, it is just a mere fact that all positions P of any moving object, including a basketball, must emerge from each other, meaning that the perception of the basketball's movement is always captured in one single line segment shape within throwing tasks. In which the current position P(0) of the basketball will always form the precise separation between the already manifest positions P(-x) and the still latent positions P(+x). In which could be further added that the perceptual image of the still latent action trajectory involves future projections that must arise from the observation of the movement of all subsequential manifest basketball positions prior to the current position P(0).

The perceptual image of the entire initial phase of the outgoing ball trajectory shape thus also represents an image of its very beginning, and at the outset of the action, we will try to guide the basketball to follow that beginning. However, even during the bridging to this first position, due to the aforementioned mutual autonomous dependency of the internal and external focus, the basketball will inevitably deviate⁴¹ from the perceptual image. It is an absolute factual given that cannot be avoided, and it

⁴⁰ Upon perusing the explanatory model, one will start to realize that the construction of a perceptual image of a latent action trajectory shape is necessary to initiate any motor action, but it doesn't need to be followed precisely. That's the essence of a highly economical system. In the initial stages of an action trajectory shape, it's not a problem at all if the basketball deviates, as long as the basketball comes closer to the endpoint. However, without a (precisely global) perceptual image of a latent action trajectory shape, motor actions cannot commence and the explanatory model introduces the term "precise global" in this context. The perceptual image of the latent action trajectory shape must precisely indicate the global (fluctuation boarders of the) direction it should take.

⁴¹ As stated in footnote 4, this precisely illustrates an optimal parsimonious model, where nothing needs to be executed very precisely, but only gives a general (albeit compelling) direction. If you were only able to move a basketball in an identical manner each time, successfully throwing basketballs to basket would become an

would quickly lead to chaotic action trajectories⁴² if there were not a system capable of mediating these deviations.

Images: The perceptual image of the initial phase of the outgoing ball trajectory shape, constructed within the tactical movement action (TMA), depicts a smooth line segment shape. However, during the actual execution, the basketball, akin to a ring in relationship to a nerve spiral⁴³, will definitely deviate at every position P within that perceptual image due to the autonomy of the internal and external focus. This necessitates redirecting the basketball back to the original perceptual image to prevent a stacking of deviations. In practice, this means that a corresponding adjustment in the remaining part of the latent action trajectory shape must be made from the micro-deviation⁴⁴. Similar to a marble in a marble run, the basketball in relationship to the initial phase of the outgoing ball trajectory shape will become a part of a continuous mutual perception-action coupling, in which the dorsal stream primarily monitors the actual position of the basketball towards the initial phase, and vice versa the ventral stream primarily monitors the initial phase towards the actual position of the basketball. The nerve spiral clearly demonstrates that this double reciprocal coupling inevitably leads to deviations c.q. to touches of the ring with the spiral, causing the basketball to follow the initial phase of the outgoing ball trajectory shape in a zigzag movement. However, the ingenious mediation of the cortical streams ensures that the action trajectory shapes appear deceptively straight.

Within there the explanatory model of the motoric movement action illustrates that the execution of action trajectory shapes indeed encompasses the essence of motor tasks, and that success hinges on the meticulous management of deviations of the action object within the action trajectory⁴⁵. Therefore, it ideally presupposes a mutually reinforcing system that continuously monitors the relationship with the action trajectory shape from the current position of the basketball, and conversely, constantly monitors the actual position of the basketball from the perceptual image of the action trajectory. The explanatory model thus implies a rather heavy correction system, and based upon current scientific literature, it concludes that the conceptual steps within the explanatory model precisely presuppose what is described (neuro-)scientifically regarding the processing of perceptions: namely, the functionality of the dorsal and ventral stream. At every time *t* or at every position P, all observations

impossible task. The task, where you only need to reduce the distance, opens up countless more possibilities and shows that the bridging process is just one part of the task.

are processed by the ventral and dorsal stream in such a way that deviations simply cannot escape

⁴² The description of the cortical streams within the motoric movement action *car driving* is particularly notable in this regard. If deviations from the driving lane on a highway do not lead to corrections the exponential product will soon lead to accidents. Deviation upon deviation will cause an exponential grow due to the fact that they belong to two complex subsystems.

⁴³ https://www.researchgate.net/publication/376888581 The nerve spiral demonstrates that random motor activity implicitly generates an internal and external focus and provides scientific evidence that the external focus can guide the action due to the in

⁴⁴ You can speak of micro-adjustments or of updating c.q. renewing the perceptual image of the remaining latent action trajectory.

⁴⁵ One must be able to stop at the right distance behind the waiting car and not bump into it, one must be able to push away an opponent in a precise *tau*-coupling process at just the right moment, and not a moment earlier or later; one must bring food precisely to the mouth, and the fingertips must also stop precisely at the coffee cup without knocking it over repeatedly.

attention. The ventral stream primarily processes deviations from the perceptual image of the entire action trajectory to the actual position of the basketball, while the dorsal stream does so vice versa, primarily from the actual position of the basketball to the perceptual image of the entire action trajectory shape. The mediation of these two processing streams leads to continuous micro-adjustments of the original perceptual image of the latent action trajectory shape, happening so ingeniously and swiftly that the absolute zigzag and accordion-like deviations barely stand out, making the executed action trajectory shapes appear deceptively straight.

4. The cortical streams mediate two autonomous groups of deviations within every conceivable action

The preceding paragraphs extensively delve into the fact that the action object will inevitably deviate from the perceptual image of the latent action trajectory shape, determined within the tactical movement action, when the action is actually performed. The occurring deviations of an action trajectory involve two autonomous phenomena⁴⁶, which relate to the words *line* and *shape* in the compound term *line segment shape*. The explanatory model demonstrates that they are observed and processed completely separately, yet simultaneously. Driving and cycling (without hand brakes) show, beyond any reasonable doubt, that the deviations in relationship to the line and shape are autonomously observed and processed.

Images: The deviations within each action trajectory shape involve two autonomous phenomena, as indicated by the explanatory model, referred to as the zigzag process and the accordion process. In car driving and cycling (without hand brakes), it becomes immediately apparent that steering exclusively influences the *movement within the shape* (!) of the action trajectory. This defines the explanatory model as mediating deviations along the x-axis and causing the zigzag process. Additionally, it becomes equally evident that using the pedals exclusively influences the movement *within the line* (!) of the action trajectory shape. This defines the explanatory model as mediating deviations along the y-axis and causing the accordion process. Therefore, in driving, it becomes crystal clear that (processing the) perceptions in relationship to the shape have absolutely nothing to do with (processing the) perceptions in relationship to the line. In which it is essential to note that processing observations regarding filling the latent line with the manifest positions P within the external (primary) focus solely involves the perception of the *tau*-value and is thus actually generated solely by the pedals of the car or bicycle. Only the speed within which the line is filled determines the duration of the action, thus finalizing the action.

Deviations along the length axis or y-axis of the action trajectory shape involve deviations of the movement of the action object over time. They are related to determining the *tau*-value⁴⁷ within a

⁴⁶ In essence, they form two complex subsystems within the larger phenomenon of the whole cortical stream operation, revealing that perceiving deviations c.q. the processing of deviations leads to an unprecedented variety of hybrid perception processes. This article does not delve further into this complexity.

⁴⁷ https://www.researchgate.net/publication/375121264 The tau-coupling process when clicking an icon shows that we absolutely do not need a motor plan Executing an external action trajectory shape within the external primary focus dictates all internal s

motor action, and deviations of the action object along the line can be characterized as an accordion process. Deviations along the width axis or x-axis of the action trajectory shape involve deviations of the movement of the action object within the shape and can be characterized as a zigzag process.

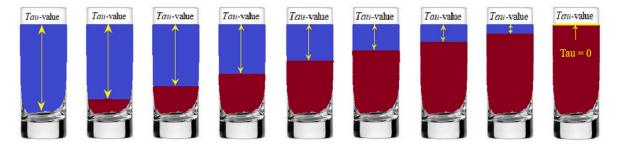

5. The zigzag process and the accordion process during the actual movement action (AMA) of a free throw in basketball

The explanatory model of he motoric movement action reveals that the zigzag process and the accordion process are inherent in every conceivable action⁴⁸. However, in other actions, demonstrating this is much more challenging than in cycling or car driving. Nevertheless, in all actions, one must consider separate pedals and a steering wheel that autonomously influence the construction and mediation of the latent action trajectory shape, which will then be processed through hybrid forms of these phenomena. While the zigzag process (the steering process) can be adequately depicted in animations for most actions, the accordion process cannot.

Images: The zigzag process in any conceivable action can easily be represented in an animation. Due to the fact that the primary focus can only be executed by the autonomous secondary focus, the action object (respectively, the letter, the pointer, and the basketball) will definitely deviate from the perceptual image of the latent action trajectory shape in width.

The accordion process (the pedal process) when executing a free throw in basketball is difficult to depict in an animation because it involves compressions and elongations of time⁴⁹. Nonetheless, similar to driving a car, you must realize that you can never move the basketball identically in time along an action trajectory shape. You can quickly observe empirically that they will vary infinitely within certain fluctuation boundaries.

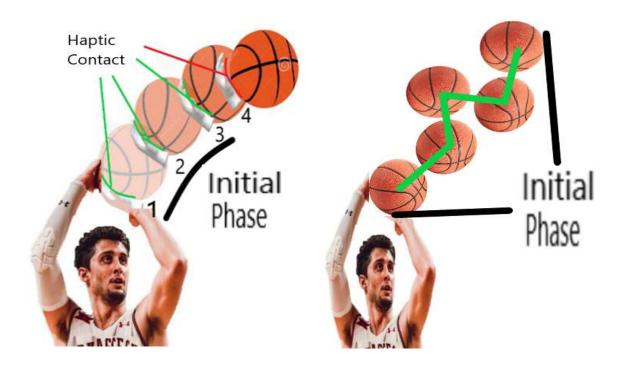

Images: In the motoric movement action *pouring*, the accordion process is still difficult to capture in an animation. However, it can be factually stated that when filling a glass, as a very rare exception,

⁴⁸ While this imposes greater demands on organismal development, conversely, it allows for a compelling demonstration of its seamless integration within an ecological framework. The dichotomy that distinguishes a separate x- and y-axis component actually constitutes the breakthrough that allows us to reduce highly complex perception processes to such seemingly simple phenomena.

⁴⁹ Wherein it should be noted for the record that the pointer does not move back within the action trajectory shape.

there are absolutely no deviations within a zigzag process. The cortical streams are fully dedicated to the accordion process during pouring.

Part 8 - The cortical streams will have to mediate throwing because we are solely capable to transfer the ball within the initial phase of an outgoing ball trajectory shape with an egocentric zigzag movement

Caught In A Line
The explanatory model of all motoric movement actions

<u>Introduction</u>

The current scientific perspective views the execution of motor actions as a single, indivisible process because it assumes only one focus in relation to the execution of a single action. It is assumed that in catching a ball or grasping a coffee cup, the perception processes are mainly concerned with these objects, upon which a motor plan (movement plan) is then formulated to get them in hand. This explanation presupposes a significant degree of automation of the movement of the hand (the fingertips) due to the dominant or leading perception of the ball or coffee cup. After all, there is only one focus to be divided. Consequently, in scientific research, the (perception of the) movement of the hand has so far taken a subordinate place.

According to this explanation, in throwing actions, such as in basketball, it is assumed that the perception processes continually remain focused on the basket. Here too, due to this leading focus, a significant degree of automation of the ball's movement is assumed, and little further attention is given to the perception processes in relation to the movement of the ball.

Since 2016, however, a new explanatory model has been developed that sheds a completely different light on the execution of motor actions. It encompasses a universal explanation that shows that the execution of any conceivable action always requires the simultaneous perception of three autonomous foci, in accordance with J.J. Gibson's theory, which compels both the movement of the animal/organism as well as the movement of the environment. In catching a ball or grasping a coffee cup, one autonomous focus remains concerned with (the movement of) the ball and/or the cup as an environmental object, which universally represents a catching action. The other two autonomous foci are concerned with the perception of the movement within the egocentrically executed action, i.e., with the movement of the hand (the fingertips) along an action trajectory shape (towards the ball and/or the coffee cup), which universally represents a throwing action. Thus, the explanatory model confirms the autonomy of perceiving (the movement of) the ball and/or the coffee cup, but also reveals the novel insight that the throwing action of the hand (fingertips) is also a completely autonomously perceived part of the action. The same clarification leads to the confirmation of the autonomous perception of the basket within throwing actions, but conversely, it is also formulated that two foci are engaged in autonomously perceiving the movement of the basketball.

Precisely because the scientific relevance of this aspect has never been recognized, this article specifically focuses on the two foci that belong to the throwing action of a ball within an egocentrically executed action trajectory shape in relation to, for example, throws in basketball. It convincingly demonstrates that the ball can solely be autonomously moved in a zigzag manner within an initial phase of an outgoing ball trajectory shape (OBT). The cortical streams, entirely in accordance with the current scientific literature, must mandatorily mediate this process, and the explanation can only be understood if one realizes that our perception processes must be egocentrically focused on the autonomous guidance of the ball within the initial phase of a that outgoing ball trajectory shape (OBT) towards the basket.

6. The tactical movement action (TMA) within the free throw in basketball encompasses the construction of a perceptual image of a latent outgoing ball trajectory shape between the current position of the ball and the basket and to reduce it to the initial phase where haptic contact between the ball and hand occurs

Supported by scientific evidence⁵⁰, the explanatory model delineates that the execution of any motor action involves two distinct sequential phases: the tactical movement action (TMA) and the actual

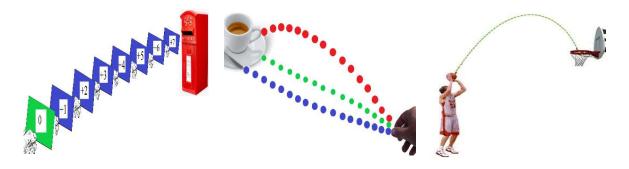

-

⁵⁰ https://www.researchgate.net/publication/372335518 You Can't Throw a Ball into a Basket You Can Solely Manipulate the Ball during Haptic Contact - Novel Insights within Free Throws and all Throwing Actions

movement action (AMA). The tactical movement action is focused solely on planning the upcoming action and must be finalized before any actual execution occurs. An essential aspect of the tactical movement action within a throwing task is to create a perceptual image of a latent action trajectory shape between the current position of the ball and the basket. Then it is equally essential to reduce this perceptual image to the phase of the intended outgoing ball trajectory shape, defined as the initial phase where haptic contact between the ball and hand exists c.q. the only timeframe in which we can egocentrically influence the ball.

The explanatory model demonstrates that during this phase, we are indeed largely focused on all physical dimensions of the basket aligning with much scientific research. However, with the recognition that a perceptual image of a latent action trajectory shape is being created, the explanatory model also arrives at a conclusion that is not yet recognized within the scientific community. The construction of a perceptual image of a latent action trajectory shape between the current position of the basketball and the basket also indicates that we strategically determine beforehand whether the space between the ball and the basket (in the very near future) can be filled or bridged by a continuous line segment shape of all dimensions of the basketball. The explanatory model provides irrefutable scientific evidence⁵¹, and you can quickly conclude from your own empirical experiences that you create a completely different action trajectory shape when there are opponents in front of the basket, and that you do not create any perceptual image of an action trajectory shape when the basket is shielded by a huge shop window.

Images: Within letter posting and grasping we also construct a perceptual image of a latent action trajectory shape during the tactical movement action (TMA) like in any conceivable motoric action, over which *all dimensions* (!) of the action object (i.e., the letter and the fingertips) will enable the action to succeed. During the actual execution within the actual movement action (AMA), akin to the basketball, one must perceive the movement of the action object during the bridging process, as only the basketball, the letter, and the fingertips are going to move c.q. can be moved egocentrically. Within the images, it is particularly noticeable that we actively perceive whether the entire path through all dimensions of the fingertips, the basketball, or the letter can be filled in a continuous action trajectory

_

⁵¹ https://www.researchgate.net/publication/371912704 The scientific proof that we primarily start with the construction of a perceptual image of an outgoing ball trajectory shape prior to the factual execution - The complete explanation of the free thro

shape c.q. we mainly perceive the "nothingness" in the vista in front of us. Because only in that void there is (empty) space to successfully execute an action.

In addition to unveiling this novelty, it is also revealed that our perceptual processes, after the tactical movement action, will primarily focus on executing the perceptual image of the initial phase, as the ball can only be influenced egocentrically during that phase. This contrasts with the traditional perspective of science, which remains constantly focused on the basket itself. So during the actual movement action (AMA), we are thus primarily engaged in the egocentric bridging process of the basketball within the initial phase c.q. in guiding the basketball according to the perceptual image of the beginning of the latent outgoing ball trajectory shape. So when the factual execution starts the basket itself is not any longer the focal point, but rather the movement of the basketball towards it c.q. the bridging of the void between (!) the current location of the ball and the basket forms the essence of the action. Another revolutionary novelty aligns with the previous thought. Although reaching the end of the action trajectory shape will eventually lead us to the completion of this task, the explanatory model, supported by scientific evidence, demonstrates that we also tactically determine beforehand whether the entire (!) space between the basketball and the basket can be filled by a continuous line segment shape of all dimensions of the basketball. This means that all positions P between the current location of the basketball and the basket are observed as actively and as crucially as the endpoint of the action trajectory shape. This realization provides a solid foundation for the fact that during the actual movement action (AMA), we are solely focused on traversing the latent positions P associated with the action trajectory shape. This implies that upon reaching position P(x), for example, somewhere midway along the action trajectory, we are mainly focused on the perception of three positions: position P(x-1), where we just came from, position P(x), where the ball is now, and position P(x+1), the perception of the next position where we need to move the basketball. In this phase, we are primarily engaged in the aforementioned bridging process and only monitor whether the gap between the basketball and the end of the initial phase icon is closing. This also reveals another essential ecological novelty, showing that during the actual movement action (AMA), we are indeed not concerned with the basket itself, but only with reducing the number of latent positions P within the initial phase of the outgoing ball trajectory shape.

7. The reciprocal dependency between the internal and external focus results in absolute deviations of the basketball within the perceptual image of the latent action trajectory shape

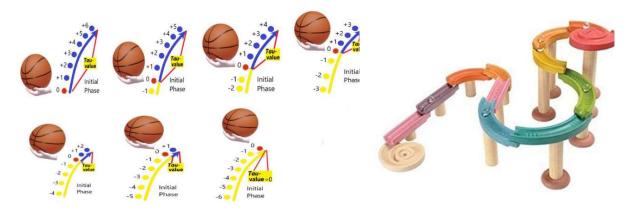

The explanatory model of the motoric movement action unequivocally illustrates within the context of throwing a basketball into a basket that two foci always arise⁵². We can only guide the basketball along an external action trajectory (from A to B) with a focus on internal movements. These foci are autonomous because the (perception of) movements occur strictly separated inside and outside the body, rendering them incompatible.

However, as the explanatory model now demonstrates that the movement of the basketball within the external action trajectory shape is going to fulfil the essence of the task, an intriguing phenomenon of reciprocal dependency emerges. Only internal motor movements towards the outer surface of the basketball can lead the basketball externally along an action trajectory shape, yet the progression of the ball within that trajectory will, as the primary focus, dictate those internal motoric movements. The inevitable consequence of this observation encompasses that it is not a matter of whether the basketball will deviate within the perceptual image of the latent initial phase of the outgoing ball trajectory shape, but rather that this is an absolute certainty. In which this absoluteness logically stems from the factual nature of the autonomous perception of both foci.

https://www.researchgate.net/publication/373139666 The execution of a free throw in basketball requires a mandatory coupling of an internal secondary focus and an external primary focus - The explanation of all functional perception processes within a? sg%5B0%5D=r-HvtLGKRrq70zRd6NHzsUpwvMuWuxJC3-rI2DafEgPlgR3JvSoKzHwM4mBUanTER6UG-bcVho7EkbCofT3Xx7Wma-BTAlkVaai4qu-V.ohtafGRQKKSH5cvL2bAs03cqvq2Ci3mWBsXtFDlIMHtV8Ox-cnGba4yjK-e7t3YNqTJnZU4RTi54cSyfrzX5ZRA& tp=eyJjb250ZXh0Ijp7ImZpcnN0UGFnZSI6In-Byb2ZpbGUiLCJwYWdlIjoicHJvZmlsZSIsInBvc2l0aW9uIjoicGFnZUNvbnRlbnQifX0

8. Within the actual movement action (AMA) the cortical streams will have to mediate the continuous flow of absolutely emerging deviations

If we now combine the two preceding paragraphs and proceed to actually throw the basketball towards the basket, our main endeavour will primarily become to initiate the bridging process of the basketball in which the perceptual image of the initial phase of the outgoing ball trajectory shape serves as an open yet compelling guiding⁵³ phenomenon. This means that we aim to *step by step* (!) reduce the distance between the current position of the basketball and the end of the initial phase, starting with the first step of moving the basketball from position P(0) to position P(+1).

Images: The explanatory model of the motoric movement action provides a tangible example with the marble in the marble run, illustrating the continuous reciprocal perception-action coupling within any conceivable motoric action. From the perspective of the marble's current position, one can perceive the relationship within the entire marble run, and vice versa, one can perceive the relationship with the marble's current position from the perspective of the entire marble run. Although all this remains invisible within throwing tasks, it is present in an equivalent manner. Because in our worldly dimensions, it is just a mere fact that all positions P of any moving object, including a basketball, must emerge from each other, meaning that the perception of the basketball's movement is always captured in one single line segment shape within throwing tasks. In which the current position P(0) of the basketball will always form the precise separation between the already manifest positions P(-x) and the still latent positions P(+x). In which could be further added that the perceptual image of the still latent action trajectory involves future projections that must arise from the observation of the movement of all subsequential manifest basketball positions prior to the current position P(0).

The perceptual image of the entire initial phase of the outgoing ball trajectory shape thus also represents an image of its very beginning, and at the outset of the action, we will try to guide the basketball to follow that beginning. However, even during the bridging to this first position, due to the aforementioned mutual autonomous dependency of the internal and external focus, the basketball will inevitably deviate⁵⁴ from the perceptual image. It is an absolute factual given that cannot be avoided, and it

⁵³ Upon perusing the explanatory model, one will start to realize that the construction of a perceptual image of a latent action trajectory shape is necessary to initiate any motor action, but it doesn't need to be followed precisely. That's the essence of a highly economical system. In the initial stages of an action trajectory shape, it's not a problem at all if the basketball deviates, as long as the basketball comes closer to the endpoint. However, without a (precisely global) perceptual image of a latent action trajectory shape, motor actions cannot commence and the explanatory model introduces the term "precise global" in this context. The perceptual image of the latent action trajectory shape must precisely indicate the global (fluctuation boarders of the) direction it should take.

⁵⁴ As stated in footnote 4, this precisely illustrates an optimal parsimonious model, where nothing needs to be executed very precisely, but only gives a general (albeit compelling) direction. If you were only able to move a basketball in an identical manner each time, successfully throwing basketballs to basket would become an

would quickly lead to chaotic action trajectories⁵⁵ if there were not a system capable of mediating these deviations.

Images: The perceptual image of the initial phase of the outgoing ball trajectory shape, constructed within the tactical movement action (TMA), depicts a smooth line segment shape. However, during the actual execution, the basketball, akin to a ring in relationship to a nerve spiral⁵⁶, will definitely deviate at every position P within that perceptual image due to the autonomy of the internal and external focus. This necessitates redirecting the basketball back to the original perceptual image to prevent a stacking of deviations. In practice, this means that a corresponding adjustment in the remaining part of the latent action trajectory shape must be made from the micro-deviation⁵⁷. Similar to a marble in a marble run, the basketball in relationship to the initial phase of the outgoing ball trajectory shape will become a part of a continuous mutual perception-action coupling, in which the dorsal stream primarily monitors the actual position of the basketball towards the initial phase, and vice versa the ventral stream primarily monitors the initial phase towards the actual position of the basketball. The nerve spiral clearly demonstrates that this double reciprocal coupling inevitably leads to deviations c.q. to touches of the ring with the spiral, causing the basketball to follow the initial phase of the outgoing ball trajectory shape in a zigzag movement. However, the ingenious mediation of the cortical streams ensures that the action trajectory shapes appear deceptively straight.

Within there the explanatory model of the motoric movement action illustrates that the execution of action trajectory shapes indeed encompasses the essence of motor tasks, and that success hinges on the meticulous management of deviations of the action object within the action trajectory⁵⁸. Therefore, it ideally presupposes a mutually reinforcing system that continuously monitors the relationship with the action trajectory shape from the current position of the basketball, and conversely, constantly monitors the actual position of the basketball from the perceptual image of the action trajectory. The explanatory model thus implies a rather heavy correction system, and based upon current scien-

tific literature, it concludes that the conceptual steps within the explanatory model precisely presuppose what is described (neuro-)scientifically regarding the processing of perceptions: namely, the functionality of the dorsal and ventral stream. At every time t or at every position P, all observations are processed by the ventral and dorsal stream in such a way that deviations simply cannot escape

impossible task. The task, where you only need to reduce the distance, opens up countless more possibilities and shows that the bridging process is just one part of the task.

⁵⁵ The description of the cortical streams within the motoric movement action *car driving* is particularly notable in this regard. If deviations from the driving lane on a highway do not lead to corrections the exponential product will soon lead to accidents. Deviation upon deviation will cause an exponential grow due to the fact that they belong to two complex subsystems.

https://www.researchgate.net/publication/376888581 The nerve spiral demonstrates that random motor activity implicitly generates an internal and external focus and provides scientific evidence that the external focus can guide the action due to the in

⁵⁷ You can speak of micro-adjustments or of updating c.q. renewing the perceptual image of the remaining latent action trajectory.

⁵⁸ One must be able to stop at the right distance behind the waiting car and not bump into it, one must be able to push away an opponent in a precise *tau*-coupling process at just the right moment, and not a moment earlier or later; one must bring food precisely to the mouth, and the fingertips must also stop precisely at the coffee cup without knocking it over repeatedly.

attention. The ventral stream primarily processes deviations from the perceptual image of the entire action trajectory to the actual position of the basketball, while the dorsal stream does so vice versa, primarily from the actual position of the basketball to the perceptual image of the entire action trajectory shape. The mediation of these two processing streams leads to continuous micro-adjustments of the original perceptual image of the latent action trajectory shape, happening so ingeniously and swiftly that the absolute zigzag and accordion-like deviations barely stand out, making the executed action trajectory shapes appear deceptively straight.

9. The cortical streams mediate two autonomous groups of deviations within every conceivable action

The preceding paragraphs extensively delve into the fact that the action object will inevitably deviate from the perceptual image of the latent action trajectory shape, determined within the tactical movement action, when the action is actually performed. The occurring deviations of an action trajectory involve two autonomous phenomena⁵⁹, which relate to the words *line* and *shape* in the compound term *line segment shape*. The explanatory model demonstrates that they are observed and processed completely separately, yet simultaneously. Driving and cycling (without hand brakes) show, beyond any reasonable doubt, that the deviations in relationship to the line and shape are autonomously observed and processed.

Images: The deviations within each action trajectory shape involve two autonomous phenomena, as indicated by the explanatory model, referred to as the zigzag process and the accordion process. In car driving and cycling (without hand brakes), it becomes immediately apparent that steering exclusively influences the *movement within the shape* (!) of the action trajectory. This defines the explanatory model as mediating deviations along the x-axis and causing the zigzag process. Additionally, it becomes equally evident that using the pedals exclusively influences the movement *within the line* (!) of the action trajectory shape. This defines the explanatory model as mediating deviations along the y-axis and causing the accordion process. Therefore, in driving, it becomes crystal clear that (processing the) perceptions in relationship to the shape have absolutely nothing to do with (processing the) perceptions in relationship to the line. In which it is essential to note that processing observations regarding filling the latent line with the manifest positions P within the external (primary) focus solely involves the perception of the *tau*-value and is thus actually generated solely by the pedals of the car or bicycle. Only the speed within which the line is filled determines the duration of the action, thus finalizing the action.

Deviations along the length axis or y-axis of the action trajectory shape involve deviations of the movement of the action object over time. They are related to determining the *tau*-value⁶⁰ within a

⁵⁹ In essence, they form two complex subsystems within the larger phenomenon of the whole cortical stream operation, revealing that perceiving deviations c.q. the processing of deviations leads to an unprecedented variety of hybrid perception processes. This article does not delve further into this complexity.

⁶⁰ https://www.researchgate.net/publication/375121264 The tau-coupling process when clicking an icon shows that we absolutely do not need a motor plan Executing an external action trajectory shape within the external primary focus dictates all internal s

motor action, and deviations of the action object along the line can be characterized as an accordion process. Deviations along the width axis or x-axis of the action trajectory shape involve deviations of the movement of the action object within the shape and can be characterized as a zigzag process.

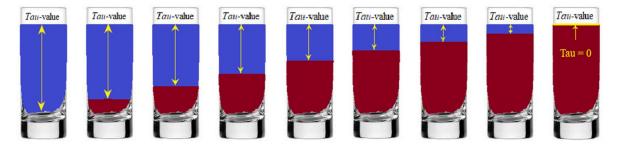

10. The zigzag process and the accordion process during the actual movement action (AMA) of a free throw in basketball

The explanatory model of he motoric movement action reveals that the zigzag process and the accordion process are inherent in every conceivable action⁶¹. However, in other actions, demonstrating this is much more challenging than in cycling or car driving. Nevertheless, in all actions, one must consider separate pedals and a steering wheel that autonomously influence the construction and mediation of the latent action trajectory shape, which will then be processed through hybrid forms of these phenomena. While the zigzag process (the steering process) can be adequately depicted in animations for most actions, the accordion process cannot.

Images: The zigzag process in any conceivable action can easily be represented in an animation. Due to the fact that the primary focus can only be executed by the autonomous secondary focus, the action object (respectively, the letter, the pointer, and the basketball) will definitely deviate from the perceptual image of the latent action trajectory shape in width.

The accordion process (the pedal process) when executing a free throw in basketball is difficult to depict in an animation because it involves compressions and elongations of time⁶². Nonetheless, similar to driving a car, you must realize that you can never move the basketball identically in time along an action trajectory shape. You can quickly observe empirically that they will vary infinitely within certain fluctuation boundaries.

Images: In the motoric movement action *pouring*, the accordion process is still difficult to capture in an animation. However, it can be factually stated that when filling a glass, as a very rare exception,

⁶¹ While this imposes greater demands on organismal development, conversely, it allows for a compelling demonstration of its seamless integration within an ecological framework. The dichotomy that distinguishes a separate x- and y-axis component actually constitutes the breakthrough that allows us to reduce highly complex perception processes to such seemingly simple phenomena.

⁶² Wherein it should be noted for the record that the pointer does not move back within the action trajectory shape.

there are absolutely no deviations within a zigzag process. The cortical streams are fully dedicated to the accordion process during pouring.
